Abstract

With the E731 apparatus at Fermilab, we have simultaneously collected 6859 $K_L$ and $K_S$ decays into $\pi^+\pi^-\gamma$. Using our large sample of $\pi^+\pi^-$ decays for normalization we have determined that the ratio $\Gamma(K^0 \rightarrow \pi^+\pi^-\gamma)/\Gamma(K^0 \rightarrow \pi^+\pi^-)$ is $(23.0 \pm 0.7) \cdot 10^{-3}$ for $K_L$ and $(7.10 \pm 0.22) \cdot 10^{-3}$ for $K_S$, for photon energies greater than 20 MeV in the kaon center-of-mass. After removing the inner-bremsstrahlung contribution, we find that the photon energy spectrum of the direct emission decay of the $K_L$ is consistent with the presence of a vector meson propagator in the form factor.
It has long been recognized\textsuperscript{1,2} that the decays $K_{L,S} \to \pi^+\pi^-\gamma$ may hold promise for illuminating the mechanisms of CP violation. The $K_L$ decay also provides a testing ground for models based on chiral perturbation theory\textsuperscript{3-5} which are relevant to understanding CP violation in rare decays such as $K_L \to \pi^0 e^+e^-$. A critical issue in these models is whether the direct-emission (DE) photon energy distribution is characterized by a pure magnetic dipole (M1) transition or manifests some additional energy dependence.\textsuperscript{6} In this letter we report the most precise results to date for the $\pi^+\pi^-\gamma$ branching ratios and demonstrate the presence of a modification to the M1 amplitude in this decay. In the following letter we demonstrate $K_L - K_S$ interference in this mode for the first time and extract new CP violation parameters for the decay.\textsuperscript{8}

The $K_S \to \pi^+\pi^-\gamma$ decay is dominated\textsuperscript{7} by inner-bremstrahlung (IB) in which a pion from the decay into $\pi^+\pi^-$ radiates a photon. However, for $K_L$ decays, the IB rate is suppressed because the underlying $\pi^+\pi^-$ decay is CP violating. This permits the more interesting CP conserving DE process, in which the photon originates from the primary decay vertex, to be significant.

The IB decay can be described very well with a pure El bremsstrahlung spectrum.\textsuperscript{7} In contrast, previous experimental results\textsuperscript{8} have supported the idea that the DE decay occurs through an M1 amplitude, modified by a form factor, $F$, which includes the effects of vector meson intermediaries. One chiral perturbation model of the decay\textsuperscript{3} suggests that $F$ is a sum of two terms, one of which contains the $\rho$ meson propagator:

\begin{equation}
F = a_1 \cdot \left((M_\rho^2 - M_K^2) + 2M_K E_\gamma^* \right)^{-1} + a_2
\end{equation}

where $E_\gamma^*$ is the energy of the photon in the center-of-mass system. The constants $M_\rho$ and $M_K$ are the masses of the neutral rho meson and neutral kaon. The coefficients $a_1$ and $a_2$ depend on the mixing angle $\theta_{\eta-\eta'}$ for the SU(3) nonet members $\eta$ and $\eta'$. This formulation leads to an energy spectrum for the emitted photon that is shifted lower in energy than the pure M1 spectrum. In other models, however, $F$ consists of a sum of amplitudes which results in no net shift in the DE photon energy spectrum.\textsuperscript{4,5}

The $\pi^+\pi^-\gamma$ decays studied here were collected by the E731 experiment at Fermilab, which measured the direct CP violation parameter $\epsilon'/\epsilon$ and concentrated on high acceptance and accurate measurement of two pion decays, both neutral and charged.\textsuperscript{9} The apparatus, described in detail elsewhere,\textsuperscript{10}
consisted of a vacuum decay vessel followed by a magnetic spectrometer. This spectrometer included four drift chambers, each incorporating four wire planes with approximately 100 micron resolution. An analyzing magnet was located between the second and third drift chambers. Following the drift chambers was an array of lead glass blocks for photon detection, with an energy resolution for photons of $2.5\% + 5\% / \sqrt{E}$. Two $K_L$ beams, one of which passed through a regenerator, allowed $K_S$ and $K_L$ decays to be collected simultaneously.

The trigger for charged decays, of which the $\pi^+\pi^-\gamma$ decays are a subset, demanded that two charged tracks traverse the detector on either side of the vertical midplane at the second drift chamber. No requirement was made on energy in the lead-glass array. In the offline analysis, each event was required to contain two tracks of momentum between 7 and 80 GeV/$c$, satisfying the trigger requirement. In addition there had to be exactly one cluster of energy of at least 1.5 GeV in the calorimeter not associated with either track. The photon energy in the kaon center-of-mass system had to be at least 20 MeV. To exclude electrons from the sample, we required $E < 0.8$, where $E$ is the cluster energy associated with a track and $p$ is the momentum of that track. Each event was also required to have a total kaon energy between 30 and 160 GeV, a reconstructed mass between 484 and 512 MeV/$c^2$ and a total transverse momentum squared of less than 250 (MeV/$c$)$^2$. To suppress the background from $\pi^+\pi^-\pi^0$ decays with one undetected photon, a cut was made on the variable

$$P_{\pi^*}^2 = \frac{[(M_{K^o}^2 - M_{\pi^*}^2 - M_\pi^2)^2 - 4M_{\pi^*}^2M_\pi^2 - 4M_{K^o}^2(p_T)^2]}{[(p_T)^2 + M_\pi^2]}$$

where $M_\pi$ is the invariant mass of the two pions and $(p_T)$ is their combined transverse momentum. For $\pi^+\pi^-\pi^0$ decays this is proportional to the squared longitudinal momentum of the $\pi^0$ in the $K$ center of mass. Barring resolution effects, $P_{\pi^*}^2$ is positive for that decay. By making our cut of $P_{\pi^*} < -0.05$ the background from the $\pi^+\pi^-\pi^0$ decay was reduced by approximately a factor of 80, while retaining 86% of the $\pi^+\pi^-\gamma$ decays, as determined from Monte Carlo simulations.

Figure 1 shows the resulting mass and $p_T^2$ spectra of the events in both beams passing all other cuts. (The events observed in the vacuum beam are mostly $K_L$ decays, while those in the regenerator beam are mostly $K_S$ decays.) The backgrounds are small. There are 7042 decays that pass all of
the cuts, 3841 of which are associated with the regenerator beam and 3201 with the vacuum beam. The background under the mass peak was estimated to be $65 \pm 10$ for the vacuum beam and $25 \pm 15$ for the regenerator beam by using the sidebands in the $p_T^2$ and mass distributions.

To isolate the separate components of the $K_L$ decay coming from DE and IB, the shape of the photon energy spectrum was used. Figure 2 shows the center of mass photon energy spectrum for the $K_L$ decays with the $K_S$ decay spectrum superimposed. The $K_S$ spectrum is shown plotted with the normalization determined by fitting the $K_L$ data to a linear combination of the $K_S$ spectrum and a pure DE spectrum obtained from a Monte Carlo simulation containing the $\rho$ propagator correction given in Equation 1. This normalized $K_S$ spectrum can then be associated with the IB component of the $K_L$ decays; when subtracted from the total spectrum the DE component for $K_L$ decays is then determined. The shape of the DE spectrum obtained in this way is not sensitive to the IB background subtraction, within the errors we observe in the fit.

An additional background for the regenerator beam which passes the event cuts is due to the $K_L$ DE component which decays downstream of the regenerator. The $K_L$ IB component which decays downstream of the regenerator is not considered a background, but is regarded as part of the $K_L$-$K_S$ coherent mixture. This latter component will be accounted for because all results for branching ratios are normalized with respect to the two charged pion decay, where the same mixture occurs. The number of DE decays downstream of the regenerator position was estimated using the vacuum beam decays and the known absorption of kaons in our regenerator. The estimate for this DE background in the regenerator beam is $93 \pm 5$ events.

A Monte Carlo simulation of the apparatus was used to determine the acceptance for this decay mode. The acceptance of our apparatus using the cuts detailed above was 10.1% for $K_L$ decays and 21.1% for $K_S$ decays. The number of reconstructed $K_S$ and $K_L$ decays into two charged pions from the same data set (totalling 370 thousand $K_L$ decays and 1.2 million $K_S$ decays) were used to normalize the $\pi^+\pi^-\gamma$ yields after correcting for their own acceptance (approximately 25% for $K_L$ and 44% for $K_S$).

A final correction was made because the requirement of having exactly one unmatched cluster in the calorimeter excludes some $\pi^+\pi^-\gamma$ events. These events contain extra clusters of energy associated with the beam or with the showering of either of the charged pions in the lead glass. An analysis was
Table 1: Measured Branching Ratios for $K_{L,S} \rightarrow \pi^+\pi^-\gamma$. All errors are combined statistical and systematic. $E^*_\gamma > 20$ MeV except where noted.

made of our large sample of $\pi^+\pi^-$ decays and it was determined that our acceptance for $\pi^+\pi^-\gamma$ events was reduced by 9.5% ± 3% due to this effect.

The final results for the numbers of events (after all selection cuts and background subtractions) and branching ratios of neutral kaons into $\pi^+\pi^-\gamma$ are given in Table 1. Also shown, for comparison to a previous result\textsuperscript{7}, is the branching ratio for $K_S$ decays where $E^*_\gamma > 50$ MeV. All errors quoted are combined statistical and systematic errors.

Systematic errors include the errors in background subtraction and extra cluster correction quoted above. An uncertainty of .25% in the normalization of the $\pi^+\pi^-$ decays is also part of the systematic error. Finally, an estimate for the error in the acceptance correction of 1.5% was obtained from the maximum variance seen in the Monte Carlo simulation after varying the cut values in the analysis.

Previous experimental results include $(1.52 \pm 0.16) \cdot 10^{-5}$ for the $K_L$ IB decay with $E^*_\gamma > 20$ MeV and $(2.89 \pm 0.28) \cdot 10^{-5}$ for the $K_L$ DE decay\textsuperscript{8}. No previous results exist for the branching ratio of the $K_S$ IB decay above 20 MeV photon energy, but above 50 MeV, the best previous result was $\Gamma(K_S \rightarrow \pi^+\pi^-\gamma)/\Gamma(K_S \rightarrow \pi^+\pi^-) = (2.68 \pm 0.15) \cdot 10^{-3}$\textsuperscript{7}. The QED prediction for this ratio is $2.56 \cdot 10^{-3}$ for $E^*_\gamma > 50$ MeV and $7.01 \cdot 10^{-3}$ for $E^*_\gamma > 20$ MeV\textsuperscript{7}. All of these results are consistent with the data presented here.

The ratio of the IB branching ratio to the two charged pion decay is consistent for $K_L$ and $K_S$ decays. Any deviations from this expectation would be a possible sign of direct CP violation in this decay mode. The
fraction of $K_L$ decays with $E_\gamma^* > 20$ MeV that are DE decays is $0.685 \pm 0.041$.

A comparison of the shape of the $K_L$ DE photon energy spectrum to the one predicted by Equation 1 is shown in Figure 3. Also shown in this figure is the comparison of the data to the DE energy spectrum of a pure M1 amplitude, one without the $\rho$ propagator form factor. The data are consistent with the energy dependent modification to the standard M1 amplitude given in Equation 1. The best fit to the data using the model from reference 4 gave $-20^0 \pm 1^0$ for $\theta_{\eta-\eta'}$ in good agreement with the commonly accepted value$^{11}$. In the notation of Equation 1 this gives $a_1/a_2 = -1.8 \pm 0.2$.

Most models assume that the radiative decays occur strictly through a dipole transition. Higher multipole transitions may lead to a CP violating asymmetry of the photon direction in the $\pi^+\pi^-$ decay frame.$^1$ For the $K_L$ data sample, we measured the average value of $\cos(\theta)$ as a function of $E_\gamma^*$, where $\theta$ is defined as the angle between the photon and the positive pion in the pion-pion rest frame. No statistically significant departure from the dipole expectation was seen in this data.

In conclusion, we have measured branching ratios for $K_{L,S} \rightarrow \pi^+\pi^-\gamma$ with improved precision. Our measurement of the $K_S$ photon energy spectrum enabled us to separate the IB and DE components in the $K_L$ decays. Our results agree both with previous measurements and with calculations of the IB component. The DE photon spectrum in $K_L$ decays shows clear evidence of additional energy dependence beyond the basic M1 shape.

We wish to thank Fermilab for the operation of the Tevatron and the MC beam line during the running of this experiment. This work was supported in part by the Department of Energy, the National Science Foundation, and the French Atomic Energy Commission. Two of us (G.D.G. and Y.W.W.) would like to acknowledge the support of the Department of Energy Outstanding Junior Investigator Awards. One of us (A.R.B.) acknowledges the support of the Robert R. McCormick Foundation, and one us us (Y.W.W.) wishes to thank the Enrico Fermi Institute of the University of Chicago for support provided by a Block Grant Award.
