(Dated: October 21, 2008)

We present the first evidence of  $WW + WZ$  production with lepton+jets final states at a hadron collider. The data correspond to  $1.07 \text{ fb}^{-1}$  of integrated luminosity collected with the D0 detector at the Fermilab Tevatron Collider in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The observed cross section for  $WW + WZ$  production is  $20.2 \pm 4.5 \text{ pb}$ , consistent with the SM prediction of  $16.1 \pm 0.9 \text{ pb}$ . The probability for background fluctuations to produce an excess equal to or larger than that observed is estimated to be  $5.4 \times 10^{-6}$ , corresponding to a significance of 4.4 standard deviations.

PACS numbers: 14.70.Fm, 14.70.Hp, 13.85.Ni, 13.85.Qk

The production of weak vector boson pairs ( $WW$ ,  $WZ$ , or  $ZZ$ ) in  $p\bar{p}$  collisions at the Fermilab Tevatron Collider has so far been observed only in fully leptonic final states [1, 2]. These processes provide tests of the electroweak sector of the standard model (SM) through the measurement of self-interactions of the vector bosons. Deviations from SM predictions for the production rates or kinematic distributions of the bosons or their decay products could indicate the presence of new physics. Final states containing two weak bosons are also relevant to searches for the Higgs boson or for new particles in extensions of the SM.

In this Letter we report the first evidence at a hadron collider for the production of a  $W$  boson decaying leptonically associated with a second vector boson  $V$  ( $V=W$  or  $Z$ ) that decays hadronically ( $WV \rightarrow \ell\nu q\bar{q}$ ;  $\ell=e, \mu$ ). The limited dijet mass resolution results in a significant overlap of the  $W \rightarrow q\bar{q}$  and  $Z \rightarrow q\bar{q}$  dijet mass peaks; therefore,  $WW$  and  $WZ$  are considered simultaneously, assuming the ratio of their cross sections as predicted by the SM. Previous searches for  $WV$  production in lepton+jets final states [3, 4] were hindered by the large background from the production of jets in association with a  $W$  boson ( $W$ +jets). The use of improved multivariate event classification and new statistical techniques [5], as well as an increased integrated luminosity, make the  $WV$  signal in lepton+jets final states more distinguishable from the  $W$ +jets background and more accessible to measurement. This analysis provides a proving ground for these advanced techniques now ubiquitous in Higgs searches at the Tevatron.

We analyze  $1.07 \text{ fb}^{-1}$  of data collected with the D0 detector [6] at a center-of-mass energy of 1.96 TeV at the Tevatron. Candidates for  $e\nu q\bar{q}$  must pass a trigger with a single electron or electron+jet(s) requirement, giving an efficiency of  $98^{+2}_{-3}\%$ . A suite of triggers for  $\mu\nu q\bar{q}$  candidates achieves an efficiency of  $100^{+0}_{-5}\%$ .

To select  $WV \rightarrow \ell\nu q\bar{q}$  candidate events, we require: a single reconstructed lepton (electron or muon) [7] with transverse momentum  $p_T > 20$  GeV and pseudorapidity  $|\eta| < 1.1$  (2.0) for electrons (muons); the imbalance in transverse energy to be  $\cancel{E}_T > 20$  GeV; and at least two jets [8] with  $p_T > 20$  GeV and  $|\eta| < 2.5$ . The highest  $p_T$  jet must satisfy  $p_T > 30$  GeV. To reduce background from processes that do not contain  $W \rightarrow \ell\nu$ , we require a “transverse”  $W$  mass [9] of  $M_T^W > 35$  GeV. The lepton must be spatially match to a track reconstructed in the central tracking system and originating from the primary vertex. Electrons (muons) must be isolated from other particles in the calorimeter (and central tracking system).

Signal and background processes containing a charged lepton are modeled via Monte Carlo (MC) simulation. The diboson signal ( $WW$  and  $WZ$ ) events are generated with PYTHIA [10] using CTEQ6L parton distribution functions (PDFs). The fixed-order matrix element (FOME) generator ALPGEN [11] with CTEQ6L1 PDFs

is used to generate  $W$ +jets,  $Z$ +jets, and  $t\bar{t}$  events to leading order at the parton level. The FOME generator COMPHEP [12] is used to produce single top quark MC samples. ALPGEN and COMPHEP are interfaced to PYTHIA for subsequent parton showering and hadronization. All simulated events undergo a GEANT-based [13] detector simulation and are reconstructed using the same programs as D0 data. Samples are normalized using next-to-leading-order (NLO) or next-to-next-to-leading-order predictions for SM cross sections, except  $W$ +jets, which is scaled to the data.

The probability for multijet events with misidentified leptons to pass all selection requirements is small; however, because of the copious production of multijet events, the background from this source cannot be ignored. For  $\mu\nu q\bar{q}$ , the multijet background is modeled with data that fail the muon isolation requirements, but pass all other selections. The normalization is determined from a fit to the  $M_T^W$  distribution. For  $e\nu q\bar{q}$ , the multijet background is estimated using a “loose-but-not-tight” data sample obtained by selecting events that pass loosened electron quality requirements, but fail the tight electron quality criteria [7]. This sample is normalized by the probability for a jet that passes the “loose” electron requirements to also pass the tight requirement. Both  $\mu\nu q\bar{q}$  and  $e\nu q\bar{q}$  multijet samples are corrected for the contributions from processes we model through MC.

Accurate modeling of the selected events is vital. The dominant background contribution is  $W$ +jets; thus the modeling of the ALPGEN  $W$ +jets sample and sources of uncertainty are studied in detail. Comparison of ALPGEN with other generators and with data shows discrepancies [14] in jet  $\eta$  and dijet angular separation. The data are therefore used to correct these quantities in the ALPGEN  $W$ +jets and  $Z$ +jets MC samples. The possible bias to this procedure from the presence of diboson signal in the data is small, but nevertheless taken into account via a systematic uncertainty. Systematic effects on the differential distributions of the ALPGEN  $W$ +jets and  $Z$ +jets MC samples due to variations of the renormalization and factorization scales and of the parameters used in the MLM parton-jet matching algorithm [15] are also considered. Uncertainties on PDFs, as well as uncertainties from object reconstruction and identification, are evaluated for all MC samples. We consider the effect of systematic uncertainty both on the normalization and on the shape of differential distributions for signal and backgrounds [16].

The signal and the backgrounds are further separated using a multivariate classifier to combine information from several kinematic variables. This analysis uses a Random Forest (RF) classifier [17]. When supplied with a set of events for training the RF creates an ensemble of decision tree classifiers [17], each designed to differentiate signal from background. The RF evaluates events by averaging the outputs from all of the trees. Thirteen

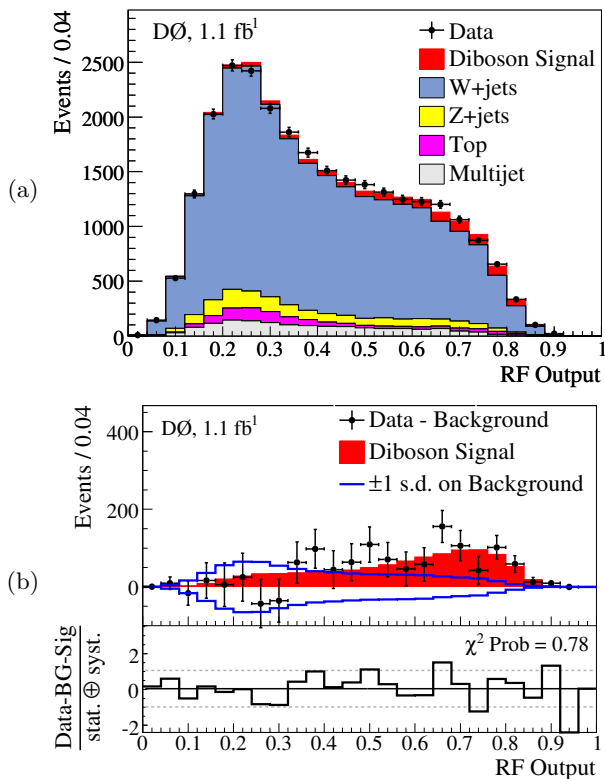

FIG. 1: (a) The RF output distribution from the combined  $e\nu q\bar{q}$  and  $\mu\nu q\bar{q}$  channels for data and MC predictions following the fit of MC to data. (b) A comparison of the signal (filled histograms) to background-subtracted data (points) in the same distribution. Also shown is the  $\pm 1$  standard deviation (s.d.) systematic uncertainty on the background prediction and the residual distance from the signal for each point divided by the total uncertainty.

TABLE I: Measured number of events for signal and each background after the combined fit (with total uncertainties as determined from the fit) and the observed number of data events.

	$e\nu q\bar{q}$ channel	$\mu\nu q\bar{q}$ channel
Diboson signal	$436 \pm 36$	$527 \pm 43$
$W$ +jets	$10100 \pm 500$	$11910 \pm 590$
$Z$ +jets	$387 \pm 61$	$1180 \pm 180$
$t\bar{t}$ + single top	$436 \pm 57$	$426 \pm 54$
Multijet	$1100 \pm 200$	$328 \pm 83$
Total predicted	$12460 \pm 550$	$14370 \pm 620$
Data	12473	14392

well-modeled kinematic variables [16] that demonstrate a difference in probability density between signal and at least one of the backgrounds, such as dijet mass and  $\cancel{E}_T$ , are used as inputs to the RF. The RF is trained using half of each MC sample. The other halves, along with the multijet background samples, are then evaluated by the RF to be used for the measurement.

The signal cross section is determined from a fit of sig-

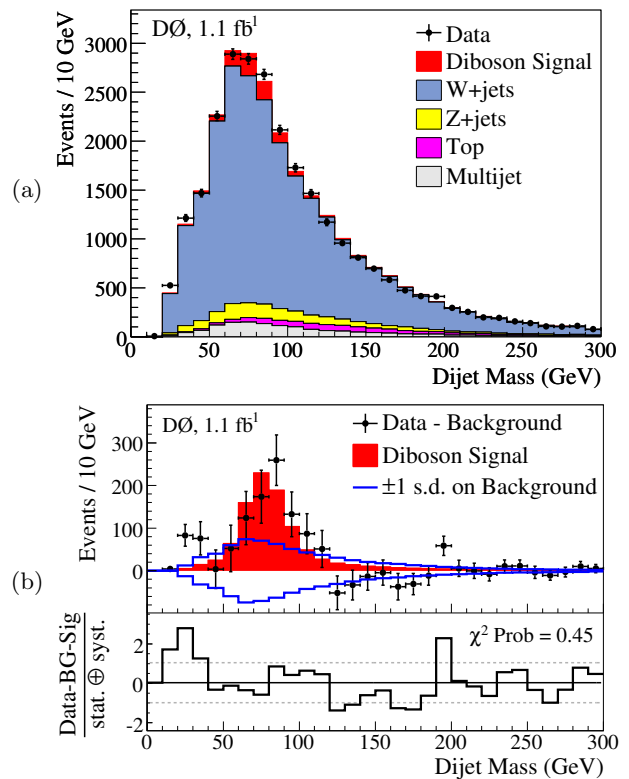

FIG. 2: (a) The dijet mass distribution from the combined  $e\nu q\bar{q}$  and  $\mu\nu q\bar{q}$  channels for data and MC predictions after the combined fit of the RF output. (b) A comparison of the signal (filled histograms) to background-subtracted data (points) in the same distribution. Also shown is the  $\pm 1$  standard deviation (s.d.) systematic uncertainty on the background prediction and the residual distance from the signal for each point divided by the total uncertainty.

nal and background RF templates to the data by minimizing a Poisson  $\chi^2$  function with respect to variations in the systematic uncertainties [5]. A Gaussian prior is used for each systematic uncertainty. Different uncertainties are assumed to be mutually independent, but those common to multiple samples or lepton channels are assumed to be 100% correlated.

The fit simultaneously varies the  $WV$  and  $W$ +jets contributions, thereby also determining the normalization factor for the  $W$ +jets MC sample. This obviates the need for using the predicted ALPGEN cross section, and provides a more rigorous approach that incorporates an unbiased uncertainty from  $W$ +jets when extracting the  $WV$  cross section. The normalization factor yielded by the fit for the  $W$ +jets ALPGEN prediction is  $1.53 \pm 0.13$ , similar to the expected ratio of NLO to LO cross sections [18]. The measured yields for signal and each background are given in Table I. Table II contains the measured  $WV$  cross section for the each channel separately and combined, showing consistent results between the channels and with the SM prediction

TABLE II: The signal cross section extracted from a simultaneous fit of the  $WV$  cross section and the normalization factor for  $W$ +jets. Also given are the expected and observed p-values obtained by comparing the measurement with pseudo-experiments assuming no signal, along with the corresponding significance in number of standard deviations (s.d.) for the corresponding one-sided Gaussian integral.

Channel	Fitted signal $\sigma$ (pb)	Expected p-value (significance)	Observed p-value (significance)
$evq\bar{q}$ RF Output	$18.0 \pm 3.7(\text{stat}) \pm 5.2(\text{sys}) \pm 1.1(\text{lum})$	$6.8 \times 10^{-3}$ (2.5 s.d.)	$3.2 \times 10^{-3}$ (2.7 s.d.)
$\mu\nu q\bar{q}$ RF Output	$22.8 \pm 3.3(\text{stat}) \pm 4.9(\text{sys}) \pm 1.4(\text{lum})$	$1.8 \times 10^{-3}$ (2.9 s.d.)	$5.2 \times 10^{-5}$ (3.9 s.d.)
Combined RF Output	$20.2 \pm 2.5(\text{stat}) \pm 3.6(\text{sys}) \pm 1.2(\text{lum})$	$1.5 \times 10^{-4}$ (3.6 s.d.)	$5.4 \times 10^{-6}$ (4.4 s.d.)
Combined Dijet Mass	$18.5 \pm 2.8(\text{stat}) \pm 4.9(\text{sys}) \pm 1.1(\text{lum})$	$1.7 \times 10^{-3}$ (2.9 s.d.)	$4.4 \times 10^{-4}$ (3.3 s.d.)

of  $\sigma(WV) = 16.1 \pm 0.9$  pb [19]. The combined fit yields a cross section of  $20.2 \pm 2.5(\text{stat}) \pm 3.6(\text{sys}) \pm 1.2(\text{lum})$  pb. The combined RF output distributions following the combined fit are shown in Fig. 1 along with a comparison between the background-subtracted data and the signal. Figure 2 shows analogous plots for the dijet mass after the combined fit of the RF output. The dominant systematic uncertainties arise from the modeling of the  $W$ +jets background and the jet energy scale [16]. The position of the dijet mass peaks in data and MC are consistent within one half standard deviation, including the relative data/MC energy scale uncertainty. As a cross check, we also perform the measurement using only the dijet mass distribution. The result, also given in Table II, is consistent with the result obtained using the RF output, though less precise.

The significance of the measurement is obtained via fits of the signal+background hypothesis to pseudo-data samples drawn from the background-only hypothesis [20]. The observed (expected) significance corresponds to the fraction of outcomes that yield a  $WV$  cross section at least as large as that measured in data (predicted by the SM). The probabilities that background fluctuations could produce the expected and observed signal in each channel, separately and combined, are shown in Table II along with the corresponding significance (number of standard deviations corresponding to the equivalent one-sided Gaussian probability).

In summary, we measure  $\sigma(WV) = 20.2 \pm 4.5$  pb (with  $V=W$  or  $Z$ ) in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. This result is consistent with the SM value of  $\sigma(WV) = 16.1 \pm 0.9$  pb [19]. The probability that the backgrounds fluctuate to give an excess equal to or larger than the excess observed in data is  $5.4 \times 10^{-6}$ , corresponding to a significance of 4.4 standard deviations. This represents the first evidence for  $WV$  production in lepton+jets events at a hadron collider and is consistent with previous measurements of  $WW$  and  $WZ$  yields in fully leptonic final states [1, 2]. This work further provides a validation of the analytical methods used in searches for Higgs bosons at the Tevatron [21].

## SUPPLEMENTAL MATERIAL

### Systematic Uncertainties

Table III gives the systematic uncertainties in percent for Monte Carlo simulations and multijet estimates. We consider the effect of systematic uncertainty both on the normalization and on the shape of differential distributions for signal and backgrounds. Though Table III lists an uncertainty for the  $W$ +jets simulation, this uncertainty is not used when measuring the diboson signal cross section, for which the  $W$ +jets normalization is a free parameter. However, the size of the uncertainty must be specified for generating the pseudo-data used in the significance estimation. Also given in the table is the contribution of each systematic uncertainty to the total systematic uncertainty of 3.6 pb on the measured cross section,  $\sigma^{\text{meas}}(WV)$ . This total systematic uncertainty is obtained from the systematic uncertainties on the parameter of the fit to the RF output,  $\sigma^{\text{meas}}(WV)/\sigma^{\text{th}}(WV)$ , multiplying them with the theoretical cross section  $\sigma^{\text{th}}(WV)$ . Therefore, the additional uncertainty on the integrated luminosity of the data sample (6.1%) is considered separately.

### Random Forest Input Variables

The 13 kinematic variables used in the Random Forest classifier are listed below. The variables are derived from characteristics of objects reconstructed from observables in each event and can be loosely classified into three categories: variables based on the kinematics of individual objects, variables based on the kinematics of multiple objects, and variables based on the angular relationships of objects. Several variables are calculated using the four-momentum of the dijet system or the leptonic  $W$  boson candidate ( $W^{\text{lept}}$ ). The dijet system is defined as the four-momentum sum of the highest  $p_T$  jet ( $\text{jet}_1$ ) and second highest  $p_T$  jet ( $\text{jet}_2$ ).  $W^{\text{lept}}$  is reconstructed from the charged lepton and the  $\cancel{E}_T$ . The neutrino from the  $W \rightarrow \ell\nu$  decay is assigned the transverse momentum from the  $\cancel{E}_T$  and a longitudinal momentum calculated from the quadratic condition satisfying  $M_W = 80.3$  GeV. Of the two possible solutions, we choose the one that minimizes the total event invariant mass.

#### • Kinematics of Individual Objects:

1. The imbalance in transverse energy ( $\cancel{E}_T$ ), which is the imbalance in transverse momentum as determined by summing the energies of

calorimeter cells and corrected for the transverse momenta of muons and the energy scale corrections for jets and electrons in the event.

2. The second highest jet  $p_T$ :  $p_T(\text{jet}_2)$ .

#### • Kinematics of Multiple Objects:

1. The “transverse  $W$  mass” reconstructed from the charged lepton and the  $\cancel{E}_T$ :  $M_T(W) = \sqrt{2 p_T^\ell \cancel{E}_T (1 - \cos(\Delta\phi(\ell, \cancel{E}_T)))}$ .
2. The  $p_T$  of the  $W^{\text{lept}}$  candidate.
3. The invariant mass of the dijet system.
4. The magnitude of the leading jet momentum perpendicular to the dijet system:  $\frac{|\vec{p}_T(\text{jet}_1 + \text{jet}_2) \times \vec{p}_T(\text{jet}_1)|}{|\vec{p}_T(\text{jet}_1 + \text{jet}_2)|}$ , where “ $\times$ ” represents the cross product relation. This variable is calculated in the rest frame of the  $W^{\text{lept}}$  candidate.
5. The magnitude of the second-leading jet momentum perpendicular to the dijet system:  $\frac{|\vec{p}_T(\text{jet}_1 + \text{jet}_2) \times \vec{p}_T(\text{jet}_2)|}{|\vec{p}_T(\text{jet}_1 + \text{jet}_2)|}$ , where “ $\times$ ” represents the cross product relation. This variable is calculated in the laboratory frame.
6. The angular separation between the two highest  $p_T$  jets, weighted by the relative transverse momentum of the second-leading jet and the  $W^{\text{lept}}$  candidate:  $\Delta R(\text{jet}_1, \text{jet}_2) \frac{p_T(\text{jet}_2)}{p_T(\ell) + \cancel{E}_T}$ . This variable is calculated in the rest frame of the  $W^{\text{lept}}$  candidate.
7. The “centrality” of the charged lepton and jets system, given by the scalar sum of transverse momenta divided by the sum of energy for the charged lepton and all jets in the event.

#### • Angular Relationships of Objects:

1. The azimuthal separation between the charged lepton and the  $\cancel{E}_T$ :  $\Delta\phi(\ell, \cancel{E}_T)$ .
2. The cosine of the angle between the dijet system and the leading jet in the laboratory frame:  $\cos(\angle(\text{jet}_1, \text{dijet}))$ .
3. The cosine of the angle between the dijet system and the second-leading jet in the laboratory frame:  $\cos(\angle(\text{jet}_2, \text{dijet}))$ .
4. Cosine of the angle between leading jet and the  $W^{\text{lept}}$  candidate:  $\cos(\angle(\text{jet}_1, W^{\text{lept}}))$ , evaluated in the rest frame of the dijet system.

TABLE III: Systematic uncertainties in percent for Monte Carlo simulations and multijet estimates. Uncertainties are identical for both lepton channels except where otherwise indicated. The nature of the uncertainty, *i.e.*, whether it refers to a differential dependence (D) or just normalization (N), is also provided. The values for uncertainties with a differential dependence correspond to the maximum amplitude of the fluctuations in the RF output. Also provided is the contribution of each source to the total systematic uncertainty of 3.6 pb on the measured cross section, which does not include the additional uncertainty of 6.1% due to the luminosity.

Source of systematic uncertainty	Diboson signal	$W$ +jets	$Z$ +jets	Top	Multijet	Nature	$\Delta\sigma$ (pb)
Trigger efficiency, $evq\bar{q}$ channel	+2/ - 3	+2/ - 3	+2/ - 3	+2/ - 3		N	< 0.1
Trigger efficiency, $\mu\nu q\bar{q}$ channel	+0/ - 5	+0/ - 5	+0/ - 5	+0/ - 5		D	< 0.1
Lepton identification	$\pm 4$	$\pm 4$	$\pm 4$	$\pm 4$		N	< 0.1
Jet identification	$\pm 1$	$\pm 1$	$\pm 1$	$\pm < 1$		D	0.3
Jet energy scale	$\pm 4$	$\pm 9$	$\pm 9$	$\pm 4$		D	1.9
Jet energy resolution	$\pm 3$	$\pm 4$	$\pm 4$	$\pm 4$		N	< 0.1
Cross section		$\pm 20^a$	$\pm 6$	$\pm 10$		N	1.1
Multijet normalization, $evq\bar{q}$ channel					$\pm 20$	N	0.9
Multijet normalization, $\mu\nu q\bar{q}$ channel					$\pm 30$	N	0.5
Multijet shape, $evq\bar{q}$ channel					$\pm 6$	D	< 0.1
Multijet shape, $\mu\nu q\bar{q}$ channel					$\pm 10$	D	< 0.1
Diboson signal NLO/LO shape	$\pm 10$					D	< 0.1
Parton distribution function	$\pm 1$	$\pm 1$	$\pm 1$	$\pm 1$		D	0.2
ALPGEN $\eta$ and $\Delta R$ corrections		$\pm 1$	$\pm 1$			D	< 0.1
Renormalization and factorization scale		$\pm 3$	$\pm 3$			D	0.9
ALPGEN parton-jet matching parameters		$\pm 4$	$\pm 4$			D	2.4

<sup>a</sup>The cross section uncertainty on  $W$ +jets is not used when measuring the diboson signal cross section (the  $W$ +jets normalization is a free parameter); however, it is necessary for generating pseudo-data used in the significance estimation.
