Subject: Collar keying of DSA325

In this note I summarize the collar keying procedure used for DSA325. Both inner and outer coils were molded with the mold components (key inserts, sizing bars, mold stop bars, etc.) at their nominal sizes and no additional molding shims were used. (This magnet is the first to have the outer coils molded with the design size key inserts.) Five mils of non-adhesive Kapton was placed between the inner coil pole turn and the pole cap to increase the prestress above that in DSA321-323[1-5]. No outer coil pole shim was used.

Collaring experiments done with DSA322[4,5] have shown that with EDMed lower collaring tooling the keys can be inserted by hand ("square key method") if the tooling is closed 4 mils beyond the nominal stop, and that with laminated lower tooling the keys can be started by about 50 mils (for "tapered key method" insertion) if the tooling is closed 6 mils less than the nominal stop. The keys are 190 mils deep and have a 10:1 wedge angle, suggesting that with laminated tooling a stop about 10 mils beyond the nominal would be required for key insertion without force.

A first collar keying attempt was made with the goal of inserting the keys without force. Initially the same shim (4 mils) was placed between the upper tooling and the upper platen as had been successfully used on DSA322 with EDMed lower tooling. The amount of collar closure was monitored by reaching into the press with a sample key and trying to insert it into the collars at the lead end. With the press closed until no lower tooling - upper platen gaps existed, full key insertion was not possible. The press shim was then increased in 2 mils increments up to 10 mils. At this point the test key could still be inserted only a little more than half way. To limit the number of compressions of the coils to high stress and until the apparent discrepancy between the expected and the observed tooling behavior was understood, the attempt to do a "square key method" insertion was abandoned. The strain gauge data from these four keying attempts are displayed in Table I and Figure 1.

A key insertion method intermediate between the successful "square" and "tapered" key assemblies of DSA322 was tried. In the "tapered key method" assembly of DSA322 the inner coil stress when the keys were started was 2.6 kpsi lower than the final value, and in the "square key method" assembly the inner coil stress before key insertion was 4.6 kpsi higher than the final stress. For DSA325 no press-tooling shims were used resulting in a compression of 6 mils more than that used for the "tapered key" assembly of DSA322 and a compression less than the "square key" assembly by an amount unknown due to the switch from EDMed to laminated tooling.

Feeler gauge measurements indicated that the press was fully closed at 7000 pump psi. To verify full closure, the vertical hydraulic pressure was increased to 8500 psi. To quantify better the amount of "zero force" key insertion possible at this point, the side cylinders were energized to 65 psi (65 lbs./in.), the pressure delivered with the regulator set to "zero," and data were recorded from the linear potentiometers connected to the side bars. The side hydraulic pressure was then increased in 500 psi steps until no change in the amount of key insertion was observed. The linear potentiometer data[6], shown in Figure 2, indicate that at zero force the keys were about 80 mils out and that full insertion occurred at 1500 lbs./in. The vertical load was then reduced to 4000 pump psi, the side load was reduced to zero, and the vertical load was reduced to zero. Visual inspection of the collared coil confirmed the full insertion of the keys.

The strain gauge data are displayed in Table II and Figure 3. The final prestresses are 11.7 and 11.8 kpsi in the inner and outer coils respectively. These are 1.2 and 5.0 kpsi lower than before key insertion and 2.8 and 7.1 kpsi lower than the peak stresses. Figure 4 shows the coil stress versus vertical hydraulic pressure before key insertion. Shown also is the expected slope[7] of 2.56 coil psi per pump psi if the press load is fully balanced by the coil and the pole and mid-plane stresses are equal. Figure 5 shows the slope $d\sigma(\text{coil})/dP(\text{press})$ versus press pressure. Even after the press is nominally closed (7000 pump psi) about 20% of the press load is still transferred to the coil. This is not understood.

The conclusions of this collaring exercise are:

- 1) The final inner coil stress is towards the high end of the desired range. Since this includes a 5 mil Kapton pole shim, the inner coils need to be molded 3-5 mils larger than these coils. In molding the next short inner coils (for DSA327) the mold cavity will be increased by 5 mils.
- 2) The final outer coil stress is higher than is needed, implying that the outer coils should be molded several mils smaller than these coils. The outer coils for DSA327 will be molded with the cavity decreased by 3 mils.
- 3) An "optimized" tapered key insertion may be defined as one in which the stress before key insertion equals the final stress. To achieve such an assembly requires that the press be closed somewhat less than was done in this case but more than was done for DSA322[5]. A shim of 2-3 mils between the lower tooling and the upper platen might meet this criterion.
- 4) That the keys were 80 mils out at "zero" side load implies that 8 mils more closure would be required for "square key" insertion. This is less than the greatest compression tried (Fig. 1). Perhaps the discrepancy results from occasional small mis-registrations between the laminated tooling and collars that could be overcome with a load of 65 lbs./in. but not by hand. The peak coil stresses with an 8 mil tooling shim (Fig. 1 and Table I) were only 0.2 and 0.3 kpsi higher in the inner and outer coils than the peak during the final key insertion.
