#### Abstract

In the paper presents data concerning to azimuthal correlations in gamma-families registered in "Pamir" experiment. The dependence of azimuthal parameter on different gamma-family characteristics and primary energy $\left(\mathrm{E}_{0}=3-30 \mathrm{PeV}\right)$ of protons and nucleus are considered. It is discussed the relation between azimuthal and alignment parameters. Obtained results are not represented in frame of the Quark-Gluon String models at the energies above 10 PeV .

## 1 Introduction:

Characteristics of hadron-nucleus (hA) interactions at the energies of $\mathrm{E}=1-100 \mathrm{PeV}$ are studied through the observation of cosmic-ray families recorded in large-scale X-ray emulsion chambers at high mountain altitudes. The experiments carried out by Pamir and Chacaltaya collaborations give an evidence for an appearance at the energies $\mathrm{E}>10 \mathrm{PeV}$ number of unusual phenomena such as binocular and alignment events, azimuthal peculiarities of families (groups of gamma-rays and hadron related by common origin) arising from nuclear-electromagnetic cascades (NEC) in atmosphere initiated by primary interactions.

These phenomena were not observed in experiments with modern accelerators and cannot be described by any theoretical model up to now. Such exotic events may be manifestation of unknown features of strong interaction at superhigh energies as well as off characteristics of primary cosmic radiation at energies of $10-100 \mathrm{PeV}$. There are some speculations on existence of new primary particles like stranglets producing unusual events. That is why primary mass determination is of great interest for solving exotic phenomena problems.

## 2 Method:

In /1/ it was proposed a new azimuthal parameter:

$$
\alpha=\frac{\sum_{\mathrm{i} \neq \mathrm{j}}^{\mathrm{n}_{\gamma}} \cos 2 \varepsilon_{\mathrm{ij}}}{\mathrm{n}_{\gamma}\left(\mathrm{n}_{\gamma}-1\right)},
$$

(where $\mathrm{n}_{\gamma}$ is the particle number in gamma-families, $\varepsilon_{\mathrm{ij}}$ is the angle between projections of i -th and j -th particles in azimuthal plane, $\left.0<\varepsilon_{\mathrm{ij}}<\pi, \mathrm{i}=1,2, \ldots, \mathrm{n}_{\gamma} ; \mathrm{j}=1,2, \ldots, \mathrm{n}_{\gamma} ; \mathrm{i} \neq \mathrm{j}\right)$ which reaches a value of $\alpha_{\max } \sim 1$ for coplanar events and equals $\alpha_{\min } \sim 0$ for the isotropic distribution of azimuthal angles. It was shown that a fast rise of azimuthal correlations as with the average transverse momentum of family particles increases observed in cosmic rays cannot be described by models based on the smooth extrapolation of interaction characteristics obtained in the accelerator experiments /2/.

Another interesting problem, that has not been explained yet, is the phenomenon of alignment of the most energetic particles $/ 3 /$. An alignment parameter is defined by

$$
\lambda_{\mathrm{n}}=\frac{\sum_{\mathrm{i} \neq \dot{i \neq k}}^{\mathrm{n}} \cos ^{\mathrm{k}} \mathrm{ij}}{\mathrm{n}(\mathrm{n}-1)(\mathrm{n}-2)}
$$

where $\varphi_{\mathrm{ij}}$ stands for the angle between two straight lines connecting the k -th center with i -th and j -th centers, n is the number of centers, $\mathrm{n}>3$. Parameter $\lambda_{\mathrm{n}}=1$ for the case of n centers aligned exactly along the straight line, while $\lambda_{n} \sim-1 /(n-1)$ corresponds to the isotropic distribution of the centers.

For the adequate interpretation of observed effects it is necessary to compare the experimental data with simulation of nuclear-electromagnetic cascades propagation through atmosphere. The experiment results are compared with Quark-Gluon Strings MCO-model /4/. In that model "normal" composition of primary particles consisting of $36 \%$ protons $p$ and $66 \%$ nucleus $A$ at the energies Eo=1 PeV and enriched by heavy nucleus above 10 PeV is assumed.

## 3 Experimental results:

In the paper the correlation relations of anizotropy and alignment parameters with spatial family characteristics that are more sensitive to strong interaction mechanism are considered. It is analysed $\mathrm{N}=798 \gamma$-families registered by Pamir Collaboration with observed energy $\Sigma \mathrm{E}_{\gamma}=100-2000 \mathrm{TeV}$, number of particles $\mathrm{n}_{\gamma} \geq 4$ and $\mathrm{E}_{\gamma}{ }^{\text {min }} \geq 4 \mathrm{TeV}$ selected within a circle of radius $\mathrm{R}_{0}=30 \mathrm{~cm}$. The families were subjected to the electromagnetic "decascading" procedure. All family particles satisfied the condition $\mathrm{Z}_{\mathrm{ik}}<\mathrm{Z}_{0}=10 \mathrm{TeV} \cdot \mathrm{mm}$, (where $\mathrm{Z}_{\mathrm{ik}}=\mathrm{R}_{\mathrm{ik}} \cdot\left(1 / \mathrm{E}_{\mathrm{i}}+1 / \mathrm{E}_{\mathrm{k}}\right)^{-1}, \mathrm{R}_{\mathrm{ik}}$ is a distance in mm between the particles, $\mathrm{E}_{\mathrm{i}}, \mathrm{E}_{\mathrm{k}}$ - their energies), were united into initial quantum. Thus the observable $\gamma$-families are transformed in the initial $\gamma_{\text {in }}$-families.

After that initial families were further subjected to "rejuvenation" procedure: the quanta satisfied the condition $f^{\prime}=\mathrm{E}_{\gamma \mathrm{i}} / \sum \mathrm{E}_{\gamma \mathrm{i}} \geq{f^{\prime}}^{\prime}{ }_{\text {min }}=0.04$, i.e. particles with energy $\mathrm{E}_{\gamma}{ }^{\text {min }} \geq 0.04 \cdot \sum \mathrm{E}_{\gamma}$, were included in the family. The anisotropy parameter $\alpha_{\text {in }}^{\prime}$ for all $\mathrm{n}_{\text {in }}^{\prime}$ initial, rejuvenated particles and the alignment parameter $\lambda^{\prime}{ }_{4 \text { in }} \geq 0.8$ for the most energetic four particles of family are calculated.

Estimation of primary energy $\mathrm{E}_{\text {est }}$ was founded on using correlation relation with $\mathrm{n}_{\text {in }}$ initial particles:

$$
\lg \mathrm{E}_{\mathrm{est}}=\mathrm{A}+\mathrm{B} \lg \mathrm{n}_{\mathrm{in}},
$$

where the coefficients A and B were derived from comparison with simulation data of the MCO model.
Fig. 1 presents correlation relations between anizotropy parameter $\alpha_{\text {in }}$ and family leteral spread $\overline{\mathrm{R}}_{\mathrm{in}}=\sum \mathrm{R}_{\mathrm{in}} / \mathrm{n}_{\text {in }}$ normalized on their average values $\left\langle\alpha_{\text {in }}^{\prime}\right\rangle,\left\langle\overline{\mathrm{R}}_{\text {in }}\right\rangle$. According to Fig. 1 a) azimuthal correlation increasing observed for "wide" families (i.e. events with value $\mathrm{R}_{\text {in }}>1.6<\mathrm{R}_{\mathrm{in}}>$ ) in experiment at the energies $E_{\text {est }}=3-100 \mathrm{PeV}$ are not represented by the model .

Since the observed family fraction originating in primary AA interactions grows with increasing energy $\mathrm{E}_{0}$ all events with $\mathrm{E}_{\text {est }}>10 \mathrm{PeV}$ was devided on two groups according to criterion $\mathrm{d}=\mathrm{n}_{\gamma} / \mathrm{n}_{\text {in }}$. The criterion $\mathrm{d}>0.7$ <d> selects mainly P-families originated from PA-interactions, the condition $\mathrm{d}<$ $0.7<\mathrm{d}>$ selects A-families. With the result that, the composition of devided families consist of $73 \% \mathrm{P}$ and $27 \%$ A-families for $\mathrm{d}>0.7<\mathrm{d}>$ and $46 \% \mathrm{P}$ and $54 \%$ A-families for $\mathrm{d}<0.7<\mathrm{d}>$. The composition of families at the energies $\mathrm{E}_{\text {est }}<10 \mathrm{PeV}$ consists of $75 \% \mathrm{P}$ and $25 \%$ A-families. As can see from 1 b ) the azimuthal parameter $\alpha_{\text {in }}^{\prime}$ increases at the energies $\mathrm{E}_{\text {est }}>10 \mathrm{PeV}$ (crosses) while at the $\mathrm{E}_{\text {est }}<10 \mathrm{PeV}$ (triangles) such dependence is expressed very little. According to this fig. azimuthal correlation increasing effect appears for "wide" families (cross) at the ultra high energies $\mathrm{E}_{\text {est }}>10 \mathrm{PeV}$ in the PAinteractions and is absent for AA-interactions (squares).

Fig. 2 presents family lateral spread $\overline{\mathrm{R}}_{\text {in }}$ distribution normalized on average value $<\overline{\mathrm{R}}_{\text {in }}>$ for the different energy regions. It is observed the considerable excess of the number of "wide" families ( $15 \pm 2 \%$ ) is not described by MCO-model at the energies above 10 PeV . (Fig. 2a).

According to table 1 fraction of "anizotropic" families (i.e.events with azimuthal parameter $\left.\alpha_{\text {in }}^{\prime}>0,26\right) \mathrm{P}_{\alpha}=\Delta \mathrm{N}\left(\alpha_{\text {in }}^{\prime}>0,26\right) / \mathrm{N}$ and aligned events $\mathrm{P}_{\lambda}=\Delta \mathrm{N}\left(\lambda_{4}>0.8\right) / \mathrm{N}\left(\underline{\alpha}_{\text {in }}^{\prime}>0,26\right)$ between "anizotropic" families essentially grows for the "wide" families region $R_{i n}>1.6<R_{i n}>$ at the energies $\mathrm{E}_{\text {est }}=4-50 \mathrm{PeV}$.

Table 2 presents the dependence of fractions of aligned between anizotropic events $P_{\lambda}$ and "wide" families $\mathrm{P}_{\mathrm{R}}=\Delta \mathrm{N}\left(\overline{\mathrm{R}}_{\text {in }}>1.6\left\langle\overline{\mathrm{R}}_{\text {in }}>\right) / \mathrm{N}\right.$ on the energy $\mathrm{E}_{\text {est }}$. As can see from the table 2 , at the energies $\mathrm{E}_{\text {est }}>10 \mathrm{PeV}$ it is observed the considerable increasing of fraction aligned and "wide" families.

These results are not represented by MCO-model. Thus, "Pamir" experimental data point to changing of strong interaction, that leads to the appearance of the "wide", coplanar and alignmented events at the superhigh energies above 10 PeV .
