This manuscript has been authored by Fermi Research Alliance, LLC under Contract No. DE-AC02-07CH11359 with the U.S. Department of Energy, Office of Science, Office of High Energy Physics.
The muon $g - 2$

Magnetic moment: $\mathbf{\mu} = \frac{-e}{2m} g_\mu \hat{S} : \quad g = 2 \quad \rightarrow \quad g = 2 + 2a_\mu$

( Dirac )

(+ radiative corrections)

- $a_\mu$ arises due to quantum corrections inherent from RQFTs (QED, SM)
- These effects manifest differently for the theoretical/experimental determination.

Theory, $a_\mu^{SM}$

→ 1948, Schwinger: $a_e = \frac{g_e - 2}{2} = \frac{\alpha}{2\pi} = 0.001162$

→ Corrections to the QED vertex function:

$\Gamma^\mu_{phys}(k_1, k_2) = \Gamma^\mu_{Dirac} + \text{radiative corrections}$

→ Must determine all SM contributions to sufficient loop order

Experiment, $a_\mu^{exp}$

→ 1948, Kusch & Foley: $g_e = 2.00238$

→ Anomalous precession frequency, $\omega_a$

$\vec{\omega}_a = \vec{\omega}_s - \vec{\omega}_c.$

$= -a_\mu \frac{Q_e}{m} \vec{B}$

Experimental measurements naturally contains all higher order effects

→ Compare $a_\mu^{SM}$ and $a_\mu^{exp}$ to rigorously test SM
The muon $g - 2$

Magnetic moment: $\hat{\mu} = \frac{e}{2m} g_\mu \hat{S}$ : 

$$ g = 2 \quad \Rightarrow \quad g = 2 + 2a_\mu $$

(Dirac) (+ radiative corrections)

- $a_\mu$ arises due to quantum corrections inherent from RQFTs (QED, SM)
- These effects manifest differently for the theoretical/experimental determination.

Theory, $a^\text{SM}_\mu$

$\rightarrow$ Today, The Muon $g - 2$ Theory Initiative

4-year long international collaborative effort:

Experiment, $a^\text{exp}_\mu$

$\rightarrow$ 2003, BNL measurement

Community approved $a^\text{SM}_\mu$ vs. BNL $a^\text{exp}_\mu$ yields $\Delta a_\mu = a^\text{exp}_\mu - a^\text{SM}_\mu = (27.9 \pm 7.6) \times 10^{-10}$

$\rightarrow$ 3.7$\sigma$ discrepancy hints at new physics beyond the SM.
The muon $g - 2$

Magnetic moment: $\tilde{\mu} = \frac{e}{2m} g_\mu \hat{S}$:

$g = 2 \quad \rightarrow \quad g = 2 + 2a_\mu$ (Dirac) (+ radiative corrections)

- $a_\mu$ arises due to quantum corrections inherent from RQFTs (QED, SM)
- These effects manifest differently for the theoretical/experimental determination.

Theory, $a_\mu^{SM}$

→ Today, The Muon g-2 Theory Initiative

4-year long international collaborative effort:

Experiment, $a_\mu^{exp}$

→ Today, Muon g-2 Experiment at Fermilab

Aiming for x4 improvement in total uncertainty.

Analysis of Run-1 data being finalised for publication.

→ Will confirm validity of Muon g-2 discrepancy and potential for BSM discovery.
Theory $g - 2$ and hadronic data

- Theory uncertainty is entirely dominated by hadronic contributions.
- These hadronic contributions rely on experimentally measured data.
- What if these data are the source of the muon $g-2$ discrepancy?
- If the data are adjusted to fix $g-2$, what impact does this have on other areas of physics?

Without theory improvements: $\Delta a_\mu \sim 6\sigma$

With theory improvements: $\Delta a_\mu > 10\sigma$
Hadronic cross section data

Experimentally measured hadronic cross section:

Muon g-2:
hadronic vacuum polarisation contribution

\[ a_\mu^{\text{had, VP}} = \frac{1}{4\pi^3} \int_{m_\pi}^{\infty} ds \ \sigma_{\text{had}}(s) K(s) \]

... sum with other SM contributions...

Runnning QED coupling:
hadronic contribution to running

\[ \Delta\alpha^{(S)}_{\text{had}}(q^2) = \frac{q^2}{4\pi\alpha^2} \int_{m_\pi}^{\infty} ds \ \sigma_{\text{had}}(s) \frac{q^2}{(q^2 - s)} \]

... evaluate at \( q^2 = M_Z^2 \) and input into global EW fit...

→ Determines \( a_\mu^{\text{SM}} \) and \( \Delta a_\mu = 3.7\sigma \)

Increase cross section so that \( \Delta a_\mu = 0 \)?
→ Solves muon g-2 discrepancy

Increase cross section so that \( \Delta a_\mu = 0 \)?
→ What happens to precision EW parameters?
Can $\Delta a_\mu$ be due to hypothetical mistakes in the hadronic $\sigma(s)$?

An upward shift of $\sigma(s)$ also induces an increase of $\Delta\alpha_{\text{had}}^{(5)}(M_Z)$.

Consider:

$$a = \int_{4m^2_\pi}^{s_u} ds \, f(s) \, \sigma(s), \quad f(s) = \frac{K(s)}{4\pi^3}, \quad s_u < M^2_Z,$$

$$b = \int_{4m^2_\pi}^{s_u} ds \, g(s) \, \sigma(s), \quad g(s) = \frac{M^2_Z}{(M^2_Z - s) (4\alpha\pi^2)}.$$

and the increase

$$\Delta\sigma(s) = \epsilon\sigma(s)$$

$\epsilon>0$, in the range:

$$\sqrt{s} \in [\sqrt{s_0} - \delta/2, \sqrt{s_0} + \delta/2]$$

Note the very different energy-dependent weighting of the integrands…

Use precise and up-to-date compilation of total hadronic cross section from KNT
The muon $g-2$ and $\Delta \alpha$ connection

- Shift KNT hadronic cross section in fully energy-dependent (point-like and binned) analysis to account for $\Delta a_\mu$. 

![Graph showing the muon g-2 and Delta alpha connection](image)

- [Graph](image) showing the muon $g-2$ and Delta alpha connection.
The muon $g-2$ and $\Delta\alpha$ connection

- Shift KNT hadronic cross section in fully energy-dependent (point-like and binned) analysis to account for $\Delta a_{\mu}$.
- Input new values of $\Delta\alpha$ into Gfitter to predict EW observables.
- Analysis greatly constrained from precise EW observables measurements and comprehensive hadronic cross section data.

$M_W$  

$\sin^2 \theta_{\text{eff}}$  

- Experimental world average · central value
- Global EW fit [$\Delta\alpha^{(S)}(M_2) + \Delta b(\sqrt{s})\delta = 100\,\text{MeV}$]
- Global EW fit [$\Delta\alpha^{(S)}(M_2) + \Delta b(\sqrt{s})\delta = 210\,\text{MeV}$]
- Global EW fit [$\Delta\alpha^{(S)}(M_2) + \Delta b(\sqrt{s})\delta = 400\,\text{MeV}$]
- Global EW fit [$\Delta\alpha^{(S)}(M_2)$ (KNT19)]
- Global EW fit [$\Delta\alpha^{(S)}(M_2) + \Delta b(\sqrt{s})\delta \pm 1\sigma$]
- Global EW fit [$\Delta\alpha^{(S)}(M_2) + \Delta b(\sqrt{s})\delta \pm 5\sigma$] at 95% CL

9  

08/24/20  Alex Keshavarzi | The muon $g-2$ and $\Delta\alpha$ connection
Bounds from the Higgs mass

Shifts in $\sigma(s)$ needed to bridge $\Delta a_\mu$ are found to be excluded above $\sqrt{s} > 0.7$ GeV at the 95%CL.

So, from EW sector, shifts to $\sigma(s)$ to bridge $g-2$ discrepancy and BMW are allowed below 0.7 GeV…?

$\rightarrow$ But, how realistic are the required shifts in $\sigma(s)$?
How realistic are the required shifts in $\sigma(s)$?

Size of missed contributions would need to be implausibly large given the robust status of the hadronic cross section measurements.
What do these shifts do the electron g-2?

\[ a_e^{\text{SM}} \text{ vs. } a_e^{\text{exp}} \text{ yields } \Delta a_e = a_e^{\text{exp}} - a_e^{\text{SM}} = (-0.89 \pm 0.36) \times 10^{-12} [2.5\sigma] \]

Shifts at low-energy that are “allowed” in muon g-2 invoke additional tension for electron g-2.
Conclusions

- The muon g-2 provides a robust test of the SM.
- Community-approved theory result from the Muon g-2 theory initiative is now released.
- The difference between theory and experiment is significant at $3.7\sigma$.
- Both the hadronic contributions to the muon g-2 and the running QED coupling depend on the measured hadronic cross section.
- This connection between g-2 and $\Delta \alpha$ allows the impact of the muon g-2 discrepancy on the EW fit to be explored.
- Increases to the hadronic cross section to solve muon g-2 discrepancy affect the predictions of EW precision observables.
- This study excludes shifts to hadronic cross section above 0.7 GeV to bridge muon g-2 discrepancy.
- However, the required shifts to the hadronic cross section below 0.7 GeV are implausibly large.
- And, these low energy shifts also worsen tension in electron g-2.

Thank you for listening.

QED fully cross checked

**Kinoshita et al. 2012:** 5-loop completed numerically (12672 diagrams):

... but 4-loop and 5-loop rely heavily on numerical integrations

Recently several independent checks of 4-loop and 5-loop diagrams:

all 4-loop graphs with internal lepton loops now calculated independently, e.g.

![Diagrams](image)

(from Steinhauser et al., PRD 93 (2016) 053017)

4-loop universal (massless) term calculated semi-analytically to 1100 digits (!) by
Laporta, arXiv:1704.06996, also new numerical results by Volkov, 1705.05800

all agree with Kinoshita et al.'s results, so **QED is on safe ground ✓**

\[ a_\mu^{QED}(\alpha(Cs)) = 116\,584\,718.931\, (104) \times 10^{-11} \]

[T. Aoyma et al, 2012, 2019, Laporta 2017,...] uncertainty dominated by \( \mathcal{O}(\alpha^6) \) contributions
EW unchanged  

Slide content by Thomas Teubner.

**Electro-Weak 1-loop diagrams:**

```
\[
\begin{align*}
\text{Diagram 1:} & \ 
\mu \rightarrow W^+ X^0, \qquad +38.9 \times 10^{-10} \\
\text{Diagram 2:} & \ 
\mu \rightarrow Z X^0, \qquad -19.4 \times 10^{-10} \\
\text{Diagram 3:} & \ 
\mu \rightarrow H X^0, \qquad \leq 3.3 \times 10^{-14}
\end{align*}
\]
```

known to 2-loop (1650 diagrams, the first full EW 2-loop calculation):

Czarnecki, Krause, Marciano, Vainshtein; Knecht, Peris, Perrottet, de Rafael

agreement, \(a_\mu^{EW}\) relatively small, 2-loop relevant: 

\[a_\mu^{EW(1+2 \text{ loop})} = (154 \pm 2) \times 10^{-11}\]

Higgs mass now known, update by Gnendiger, Stoeckinger, S-Kim,

\[a_\mu^{EW(1+2 \text{ loop})} = (153.6 \pm 1.0) \times 10^{-11}\]

\[\checkmark\]

compared with \(a_\mu^{QED} = 116 \ 584 \ 718.951 (80) \times 10^{-11}\)

Uncertainty dominated by hadronic contributions.
Dispersive HLbL

Slide content by Aida El-Khadra.

Had never been achieved before the theory initiative...

Dispersive approach:
[Colangelo at al, 2014; Pauk & Vanderhaegen 2014; ...]

- Model independent
- Significantly more complicated than for HVP
- Provides a framework for data-driven evaluations
- Can also use lattice results as inputs

Target: ≤ 10% total error

- Consistent with other lattice results
- Total uncertainty is \(\sim \div 4\) ...
- Consistent w/ BNL experiment ("no new physics" scenario) !
- \(\ldots \) and comparable to R-ratio
- \(3.1\sigma\) larger than DHMZ'19, \(3.9\sigma\) than KNT'19 ?

Currently being scrutinised by theory initiative for white paper round 2...

Fermilab 22 08/24/20 Alex Keshavarzi | The muon g-2 and \(\Delta\alpha\) connection
The Muon g-2 and the bounds on the Higgs boson mass  Marciano, Passera and Sirlin (2008)

“… if the hadronic cross section is shifted up in energy regions centred above ∼ 1.2 GeV to bridge the muon g–2 discrepancy, the Higgs mass upper bound becomes inconsistent with the LEP lower limit.”
Hadronic vacuum polarization: \((g - 2)_\mu\) versus global electroweak fits

- Using global EW fit (HEPFitter) results in a tension with the BMW result.
- A significant shift in HVP exacerbates tensions within the EW fit \(\rightarrow\) inconsistent W mass prediction.
- Does not weaken the case for BSM physics, but to some extent shifts it from \((g - 2)_\mu\) to the EW fit.

- Results cannot rule out BMW.
- Analysis uses strong assumptions \(\rightarrow\) energy independent shifts of the cross section.
- Incorporating energy-dependence at low energies is crucial.
**Energy dependence of BMW** Slide content by Laurent Lellouch.

- Crivellin et al '20, most aggressive scenario: our results suggest a 4.2σ overshoot in $\Delta^{(5)}_{\text{had}}(M^2_Z)$ compared to result of fit to EWPO.

- Assume same 2.8% relative deviation from R-ratio as we find in $a^\text{LO-HVP}_\mu$.

- Hypothesis is not consistent w/ BMWc '17 nor new preliminary result.

Differences between BMW and KNT are contained within low-energy, non-perturbative hadronic domain.

**Note:** Comparison is between time-like $\Delta\alpha$ from $e^+e^-$ data and space-like $\Delta\alpha$ from lattice in Euclidean space-time.
How realistic are the required shifts in $\sigma(s)$?

Size of missed contributions would need to be implausibly large given the robust status of the hadronic cross section measurements.
Lattice QCD  Slide content by Aida El-Khadra.

\[
\mathcal{L}_{\text{QCD}} = \sum_f \bar{\psi}_f (\mathcal{D} + m_f) \psi_f + \frac{1}{4} \text{tr} F_{\mu\nu} F^{\mu\nu}
\]

- discrete Euclidean space-time (spacing \(a\))

- finite spatial volume \((L)\)
- finite time extent \((T)\)

adjustable parameters

- lattice spacing: \(a \rightarrow 0\)
- finite volume, time: \(L \rightarrow \infty, T > L\)
- quark masses \((m_f)\):
  \[M_{H, \text{lat}} = M_{H, \text{exp}}\]
  \[m_f \rightarrow m_{f, \text{phys}}\]

Integrals are evaluated numerically using monte carlo methods.

- tune using hadron masses
- extrapolations/interpolations
Target: ~0.2% total error

- Dispersion relation + experimental data for $e^+e^- \rightarrow$ hadrons (and $\tau$ data)
  - current uncertainty ~0.5%
  - can be improved with more precise experimental data
  - new experimental measurements expected/ongoing at BaBar, BES-III, Belle-II, CMD-3, SND, KEDR, KLOE, ...

- Challenges:
  - below ~2 GeV: sum > 30 exclusive channels: $2\pi$, $3\pi$, $4\pi$, $5\pi$, $6\pi$, $2K$, $2K\pi$, $2K2\pi$, $\eta\pi$, ... (use isospin relations for missing channels)
  - above ~1.8 GeV:
    - inclusive, pQCD (away from flavor thresholds)
    - narrow resonances ($J/\psi$, $\Upsilon$, ..)
  - Combine data from different experiments/measurements: understanding correlations, sources of sys. error, tensions...
  - include FS radiative corrections
Dispersive HVP  
Slide content by Aida El-Khadra.
**Lattice HVP** Slide content by Aida El-Khadra.

- **Target:** < 0.5% total error
- **light-quark connected contribution,** \( a_{\mu,ud}^{HLO} \): 
  - ~90% of total, with 1-3% error
- **“heavy” flavor contributions,** \( a_{\mu,s}^{HLO}, a_{\mu,c}^{HLO}, a_{\mu,b}^{HLO} \): 
  - ~8%, 2%, 0.05% of total \( a_{\mu}^{HLO} \), can be calculated with sufficient precision
- **disc. contribution:** 
  - ~2% of total \( a_{\mu}^{HLO} \), contributes ~0.3-1% error to \( a_{\mu}^{HLO} \)
- **Isospinbreaking (QED + \( m_u \neq m_d \)) corrections:** 
  - ~1% of total \( a_{\mu}^{HLO} \), contribute ~0.3-1% error

Lepton moments summary

Slide content by Aida El-Khadra.

Sensitivity to heavy new physics:

\[ a_\ell^{NP} \sim \frac{m_\ell^2}{\Lambda^2} \]

\[ (m_\mu/m_e)^2 \sim 4 \times 10^4 \]

Ongoing experimental programs for improved measurements of \( \alpha \)

[S. Guellati-Khelifa (Paris), Z. Pagel (Berkeley) @ INT workshop]
On constraints between $\Delta \alpha$ and g-2

- Claim that it is possible to construct spectral functions which reproduce both BMW and KNT, inducing only a very small change in $\Delta \alpha$.
- Constrain the contribution to the hadronic running that can be related to a particular dimension-6 operator (or, equivalently, to the first moment of the HVP function).
- Implication is there is a bound that restricts all effects in the hadronic running to the small piece that is related to this first moment (the first term in Eq. (6) of the attached notes). This is not the case.
- Needs to go past just first moment.
- Additionally, these shifts in the cross section at such low energies will have to be enormous.
- But, provides interesting comparison between time-like and space-like $\Delta \alpha$. 
μ-e elastic scattering to measure $a_{\mu}^{\text{HVP}}$

M. Passera @ HVP KEK 2018 [A. Abbiendi et al, arXiv:1609.08987, EPJC 2017]

$\Delta \alpha_{\text{had}}(t)$ is the hadronic contribution to the running of $\alpha$ in the space-like region. It can be extracted from scattering data!

\[
a_{\mu}^{\text{HLO}} = \frac{\alpha}{\pi} \int_0^1 dx \ (1 - x) \Delta \alpha_{\text{had}}[t(x)]
\]

\[
t(x) = \frac{x^2 m_{\mu}^2}{x - 1} < 0
\]

- use CERN M2 muon beam (150 GeV)
- Physics beyond colliders program @ CERN
- LOI June 2019
- Jan 2020: SPSC recommends pilot run in 2021
- goal: run with full apparatus in 2023-2024
\( \mu - e \) elastic scattering to measure \( g^\text{HVP}_\mu \)

C. Carloni @ g-2 INT workshop [A. Abbiendi et al, arXiv:1609.08987, EPJC 2017]

- requires calculations of radiative corrections [M. Fael @ g-2 INT workshop]
- complement region not accessible to experiment with LQCD calculation [M. Marinkovic @ g-2 INT workshop]
