where f'_q ($q = s, d$) is the B_q^0 fraction in a sample of semileptonic b-hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q \tau_b)$, where τ_b is the average b-hadron lifetime. Hence $\overline{\chi}$ measurements performed at LEP [85] and Tevatron [86,87], together with χ_d given in Eq. (75.16) and the very good approximation $\chi_s = 1/2$ (in fact $\chi_s = 0.499312 \pm 0.000004$ from Eqs. (75.5), (75.17) and (75.20)), provide constraints on f_d and f_s.

The LEP experiments have measured $\mathcal{B}(\bar{b} \to B_s^0) \times \mathcal{B}(B_s^0 \to D_s^- \ell^+ \nu_\ell X)$ [88], $\mathcal{B}(b \to \Lambda_b^0) \times \mathcal{B}(\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell X)$ [89], and $\mathcal{B}(b \to \Xi_b^-) \times \mathcal{B}(\Xi_b^- \to \Xi^- \ell^- \overline{\nu}_\ell X)$ [90] from partially reconstructed final states including a lepton, $f_{\rm baryon}$ from protons identified in b events [91], and the production rate of charged b hadrons [92]. The b-hadron fraction ratios measured at CDF are based on double semileptonic $K^*\mu\mu$ and $\phi\mu\mu$ final states [93] and lepton-charm final states [94]; in addition CDF and DØ have both measured strange b-baryon production [95]. A combination of the available information from LEP and Tevatron yields, under the constraints $f_u = f_d$, $f_u + f_d + f_s + f_{\rm baryon} = 1$ and Eq. (75.22), the averages of the first two columns of Table 75.1.

Fraction ratios have been studied by LHCb using fully reconstructed hadronic B_s^0 and B_d^0 decays as well as semileptonic decays of Λ_b^0, B_s^0, B_d^0 and B_u (see [97] and references therein). ATLAS has measured f_s/f_d using $B_s^0 \to J/\psi\phi$ and $B^0 \to J/\psi K^{*0}$ decays [98]. Both CDF and LHCb observe that the ratio $f_{\Lambda_b^0}/(f_u + f_d)$ decreases with the transverse momentum of the lepton+charm system, indicating that the b-hadron fractions are not the same in different environments. LHCb also observes that $f_s/(f_u + f_d)$ decreases with transverse momentum. The third column of Table 75.1 displays the LHC measurements of $f_s/f_u = f_s/f_d$, which increase slowly with centre-of-mass energy. The B_c^+ fraction has been measured for the first time by LHCb to be (0.26±0.06)% [99].

75.6 CP-violation studies

Evidence for CP violation in B_q^0–$\overline{B}_q^0$ mixing has been searched for, both with flavor-specific and inclusive B_q^0 decays, in samples where the initial flavor state is tagged, usually with a lepton from the other b-hadron in the event. In the case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\rm SL}^q = \frac{N(\overline{B}_q^0(t) \to \ell^+ \nu_\ell X) - N(B_q^0(t) \to \ell^- \overline{\nu}_\ell X)}{N(\overline{B}_q^0(t) \to \ell^+ \nu_\ell X) + N(B_q^0(t) \to \ell^- \overline{\nu}_\ell X)} \simeq 1 - |q/p|_q^2 \quad (75.23)$$

has been measured either in time-integrated analyses at CLEO [49,100], BaBar [101], CDF [102], DØ [103–105] and LHCb [106], or in time-dependent analyses at LEP [40,107], BaBar [50,108] and Belle [109]. In the inclusive case, also investigated at LEP [107,110], no final-state tag is used, and the asymmetry [111]

$$\frac{N(\overline{B}_q^0(t) \to \text{all}) - N(B_q^0(t) \to \text{all})}{N(\overline{B}_q^0(t) \to \text{all}) + N(B_q^0(t) \to \text{all})} \simeq \mathcal{A}_{\rm SL}^q \left[\sin^2\left(\frac{\Delta m_q\, t}{2}\right) - \frac{x_q}{2}\sin(\Delta m_q\, t)\right] \quad (75.24)$$

must be measured as a function of the proper time to extract information on CP violation. In addition LHCb has studied the time dependence of the charge asymmetry of $B^0 \to D^{(*)-}\mu^+\nu_\mu X$ decays without tagging the initial state [112], which would be equal to

$$\frac{N(D^{(*)-}\mu^+\nu_\mu X) - N(D^{(*)+}\mu^-\bar{\nu}_\mu X)}{N(D^{(*)-}\mu^+\nu_\mu X) + N(D^{(*)+}\mu^-\bar{\nu}_\mu X)} = \mathcal{A}_{\rm SL}^d \frac{1 - \cos(\Delta m_d\, t)}{2} \quad (75.25)$$

in absence of detection and production asymmetries.

The DØ collaboration measured a like-sign dimuon charge asymmetry in semileptonic b decays that deviates by $2.8\,\sigma$ from the tiny Standard Model prediction and concluded, from a more refined analysis in bins of muon impact parameters, that the overall discrepancy is at the level of $3.6\,\sigma$ [103]. In all other cases, asymmetries compatible with zero (and the Standard Model [10,11]) have been found, with a precision limited by the available statistics. Several of the analyses at high energy don't disentangle the B_d^0 and B_s^0 contributions, and either quote a mean asymmetry or a measurement of $\mathcal{A}_{\rm SL}^d$ assuming $\mathcal{A}_{\rm SL}^s = 0$: we no longer include these in the average. An exception is the dimuon DØ analysis [103], which separates the two contributions by exploiting their dependence on the muon impact parameter cut. The resulting measurements of $\mathcal{A}_{\rm SL}^d$ and $\mathcal{A}_{\rm SL}^s$ are then both compatible with the Standard Model. They are also correlated. We therefore perform a two-dimensional average of the measurements of Refs. [49,50,100,101,103–106,108,109,112] and obtain [8]

$$\mathcal{A}_{\rm SL}^d = -0.0021 \pm 0.0017 \Leftrightarrow |q/p|_d = 1.0010 \pm 0.0008\,, \quad (75.26)$$

$$\mathcal{A}_{\rm SL}^s = -0.0006 \pm 0.0028 \Leftrightarrow |q/p|_s = 1.0003 \pm 0.0014\,, \quad (75.27)$$

with a correlation coefficient of -0.054 between $\mathcal{A}_{\rm SL}^d$ and $\mathcal{A}_{\rm SL}^s$. These results show no evidence of CP violation and are compatible with the very small Standard Model predictions, $\mathcal{A}_{\rm SL}^{d,{\rm SM}} = -(4.73 \pm 0.42) \times 10^{-4}$ and $\mathcal{A}_{\rm SL}^{s,{\rm SM}} = +(2.06 \pm 0.18) \times 10^{-5}$ [9], but have insufficient precision yet to constrain the Standard Model.

CP violation induced by B_s^0–$\overline{B}_s^0$ mixing in $b \to c\bar{c}s$ decays, which is controlled by the small weak phase $\phi_s^{c\bar{c}s}$, has been a field of very active study in the past decade. In addition to the previously mentioned $B_s^0 \to J/\psi K^+K^-$ (including $B_s^0 \to J/\psi\phi$) and $B_s^0 \to \psi(2S)\phi$ studies, the decay modes $B_s^0 \to J/\psi\pi^+\pi^-$ (including $B_s^0 \to J/\psi f_0(980)$) [73,113] and $B_s^0 \to D_s^+ D_s^-$ [31] have also been analyzed by LHCb to measure $\phi_s^{c\bar{c}s}$, without the need for an angular analysis. The $J/\psi\pi^+\pi^-$ final state has been shown indeed to be (very close to) a pure CP-odd state [114]. In the $B_s^0 \to J/\psi\phi$ and $B_s^0 \to J/\psi K^+K^-$ analyses, $\phi_s^{c\bar{c}s}$ is obtained together with several other observables, including $\Delta\Gamma_s$, Γ_s, the longitudinal and perpendicular ϕ polarisation amplitudes, the S-wave amplitude, and strong phases. In order to account for all correlations, the full sets of measurements provided by the different analyses are

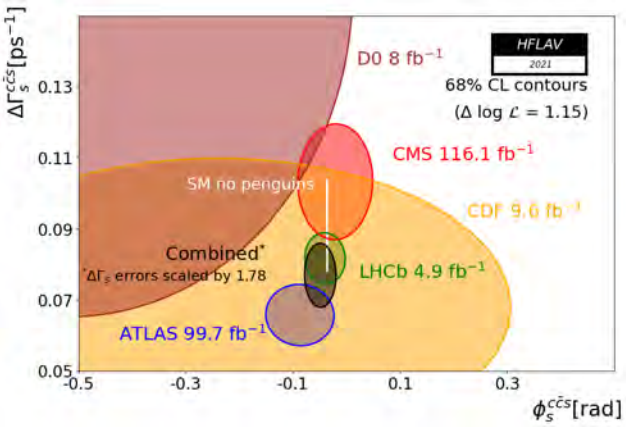

Figure 75.3: 68% CL contours in the $(\phi_s^{c\bar{c}s}, \Delta\Gamma_s)$ plane, showing all measurements from CDF [77], DØ [78], ATLAS [79], CMS [33, 80] and LHCb [30, 31, 73, 81–83, 113]. Their average [8] is represented as the black ellipse, where the combined uncertainty on $\Delta\Gamma_s$ has been multiplied by 1.78. The very thin white rectangle represents the Standard Model predictions of $\phi_s^{c\bar{c}s}$ [63] and $\Delta\Gamma_s$ [9].

combined in a multi-dimensional fit [8] of which $\phi_s^{c\bar{c}s}$ is just one of the free parameters. As already mentioned the $B_s^0 \to J/\psi\phi$ analyses of ATLAS, CMS and LHCb show a poor overall compatibility, mostly in the lifetime and angular parameters, corresponding approximately 3 standard deviations. Therefore, scale factors are applied on the combined uncertainty of each parameter where a discrepancy arises. For the parameters already in agreement, such as $\phi_s^{c\bar{c}s}$, no scale factor is applied. The combined result based on all published analyses [30, 31, 33, 73, 77–83, 113] is

$$\phi_s^{c\bar{c}s} = -0.049 \pm 0.019\,. \tag{75.28}$$

A two-dimensional projection of the overall situation in the $(\phi_s^{c\bar{c}s}, \Delta\Gamma_s)$ plane is shown in Fig. 75.3.

The experimental determination of $\phi_s^{c\bar{c}s}$ is still statistically limited. It is consistent with the Standard Model prediction, which is equal to $-2\beta_s = -2\arg(-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)) = -0.0368\,^{+0.0006}_{-0.0009}$ [63] assuming negligible Penguin pollution.

75.7 Summary

B^0–$\overline{B}^0$ mixing has been and still is a field of intense study. The mass differences in the B_d^0–$\overline{B}_d^0$ and B_s^0–$\overline{B}_s^0$ systems are known to relative precisions of 0.38% and 0.03%, respectively. The non-zero decay width difference in the B_s^0–$\overline{B}_s^0$ system is well established, with a relative difference of $\Delta\Gamma_s/\Gamma_s = (12.8\pm0.7)\%$, meaning that the heavy state of the B_s^0–$\overline{B}_s^0$ system lives $\sim 14\%$ longer than the light state. In contrast, the relative decay width difference in the B_d^0–$\overline{B}_d^0$ system, $\Delta\Gamma_d/\Gamma_d = (0.1 \pm 1.0)\%$, is still consistent with zero. CP violation in B_d^0–$\overline{B}_d^0$ or B_s^0–$\overline{B}_s^0$ mixing has not been observed yet, with precisions on the semileptonic asymmetries below 0.3%. CP violation induced by B_s^0–$\overline{B}_s^0$ mixing in $b \to c\bar{c}s$ transitions has not yet been observed either, with an uncertainty on the $\phi_s^{c\bar{c}s}$ phase of 19 mrad. All observations so far remain consistent with the Standard Model expectations.

However, the measurements where New Physics might show up are still statistically limited. More results are awaited from the LHC experiments and Belle II, with promising prospects for the investigation of the CP-violating phase $\arg(-M_{12}/\Gamma_{12})$ and an improved determination of $\phi_s^{c\bar{c}s}$.

Mixing studies have clearly reached the stage of precision measurements, where much effort is needed, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the B_d^0 and B_s^0 mixing amplitudes (magnitudes and phases) with all other measured flavor-physics observables will be possible within the Standard Model, leading to very tight limits on (or otherwise a long-awaited surprise about) New Physics.

76. Semileptonic b-Hadron Decays, Determination of V_{cb}, V_{ub}

Revised August 2021 by A.X. El-Khadra (Physics, Illinois U.) and P. Urquijo (School of Phys. U. of Melbourne).

76.1 Introduction

Precision determinations of $|V_{ub}|$ and $|V_{cb}|$ are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in B decays. The length of the side of the unitarity triangle opposite the well-measured angle β is proportional to the ratio $|V_{ub}|/|V_{cb}|$; its precise determination is a high priority of the heavy-flavor physics program.

The transitions $b \to c\ell\bar{\nu}_\ell$ and $b \to u\ell\bar{\nu}_\ell$ ($\ell = e, \mu$) each provide two avenues for determining these CKM matrix elements, namely through measurements of inclusive decay rates, $\bar{B} \to X\ell\bar{\nu}_\ell$ with a sum over all possible hadronic states X or of exclusive rates, where the final state hadron is a specific meson ($X = D$, D^*, π, ρ etc.).

Purely leptonic decays, such as $B_c^- \to \tau\bar{\nu}$, $B^- \to \tau\bar{\nu}$, and $B^- \to \mu\bar{\nu}$, provide a third avenue that is theoretically very simple (see the RPP mini-review [1]). However, we do not use this information at present since none of the measurements have reached a competitive level of precision. Hence the results presented here are solely obtained from exclusive and inclusive semileptonic b-hadron decays. This article and the values quoted here update the previous review [2].

The theoretical methods underlying the different determinations of $|V_{qb}|$ are quite mature. The theoretical approach for inclusive determinations uses the fact that the mass m_b of the b quark is large compared to the scale $\Lambda_{\rm QCD}$ that determines low-energy hadronic physics. Thus the basis for precise calculations is a systematic expansion in powers of Λ/m_b, where $\Lambda \sim 500 - 700$ MeV is a hadronic scale of the order of $\Lambda_{\rm QCD}$. Such an expansion can be formulated in the framework of an effective field theory which is described in a separate RPP mini-review [3]. Exclusive determinations rely on non-perturbatively calculated form factors, that encode the low-energy dynamics of the hadronic transition. Here, lattice QCD provides an, in principle, ab-initio method to calculate the non-perturbative QCD contributions to the exclusive decay amplitudes. Thanks to a combination of improved theoretical methods, better algorithms, and large increases in computational power, precise lattice QCD results are now available for the processes that are used in exclusive $|V_{ub}|$ and $|V_{cb}|$ determinations. State-of-the-art lattice QCD calculations are based on gauge-field ensembles that include realistic sea quark effects for degenerate up/down and strange quarks (aka $2+1$-flavor ensembles), and increasingly, also for charm (aka $2+1+1$-flavor ensembles). They employ ensembles generated at three (or more) lattice spacings, different spatial volumes, among other parameter variations to allow for quantification of the underlying systematic errors, and include detailed systematic error analyses. This is described in a separate RPP mini-review [4]. The lattice-QCD results discussed in this review are all state-of-the art with fully quantified uncertainties, and therefore play a central role in exclusive $|V_{qb}|$ determinations. In the case of exclusive $\bar{B} \to D^{(*)}\ell\bar{\nu}_\ell$ decays, heavy quark symmetry (HQS) and heavy quark effective theory (HQET) yield constraints on the form factors that can be used to improve exclusive $|V_{cb}|$ determinations, especially when lattice QCD form factor results are incomplete, as was the case until very recently for $\bar{B} \to D^*\ell\bar{\nu}_\ell$. Light-cone sum rules (LCSR) provide another nonperturbative approach to compute form factors. However, while the lattice-QCD results employed in this review have well-quantified uncertainties, LCSR results suffer, in general, from hard-to-quantify systematic errors. The two methods typically provide results in opposite regions of phase space. Lattice-QCD calculations work best at low hadronic recoil or high momentum transfer (q^2) to the leptons, while LCSR calculations provide estimates at high recoil, near $q^2 = 0$.

The measurements discussed in this review are of branching fractions, ratios of branching fractions, and decay kinematic distributions. The determinations of $|V_{cb}|$ and $|V_{ub}|$ also require a measurement of the total decay widths of the corresponding b hadrons, determined from lifetimes, which is the subject of a separate RPP mini-review [5]. The measurements of inclusive semileptonic decays relevant to this review come primarily from e^+e^- B factories operating at the $\Upsilon(4S)$ resonance, while the measurements of exclusive semileptonic decays come from both the e^+e^- B factories and from the LHCb experiment at CERN.

Semileptonic B-meson decay amplitudes to electrons and muons are well measured and consistent with Standard Model W-boson exchange. As they are expected to be insensitive to the effects of non-Standard-Model physics, they are used to extract $|V_{qb}|$. However, semileptonic decays to tau-lepton final states, such as $\bar{B} \to D^{(*)}\tau\bar{\nu}_\tau$, may be sensitive to effects from beyond the Standard Model particles due to the large mass of the τ lepton. The currently observed tensions between Standard Model theory and experiment for these decays indicate that semitauonic decays must be studied further.

Many of the numerical results quoted in this review have been provided by the Heavy Flavor Averaging Group (HFLAV) [6].

76.2 Determination of $|V_{cb}|$

Summary: The determination of $|V_{cb}|$ from inclusive decays has a relative uncertainty of about 2%; the limitations arise mainly from our ignorance of higher-order perturbative and non-perturbative corrections. Exclusive $\bar{B} \to D^*\ell\bar{\nu}_\ell$ decays provide a determination of $|V_{cb}|$ with a relative precision of about 2%, with comparable contributions from theory and experiment to the total uncertainty; the value determined from $\bar{B} \to D\ell\bar{\nu}_\ell$ decays is consistent and has an uncertainty of 3%. However, as discussed below, recent work has raised questions about determinations based on the CLN parameterization, and we choose to quote a result obtained from a less constraining analysis.

The values obtained from the inclusive and exclusive B decay determinations discussed below are:

$$|V_{cb}| = (42.2 \pm 0.8) \times 10^{-3} \quad \text{(inclusive)} \tag{76.1}$$

$$|V_{cb}| = (39.4 \pm 0.8) \times 10^{-3} \quad \text{(exclusive)}. \tag{76.2}$$

An average of these determinations has $p(\chi^2) = 1\%$, so we scale the error by $\sqrt{\chi^2/1} = 2.6$ to find

$$|V_{cb}| = (40.8 \pm 1.4) \times 10^{-3} \quad \text{(average)}. \tag{76.3}$$

Given the only marginal consistency, of approximately 2.4 σ, this average should be treated with caution.

76.2.1 $|V_{cb}|$ *from exclusive decays*

Exclusive determinations of $|V_{cb}|$ make use of semileptonic B decays into the ground state charmed mesons D and D^*. The corresponding hadronic matrix elements can be parameterized in terms of six independent form factors, which depend on the variable $w \equiv v \cdot v'$, where v and v' are the four velocities of the initial and final-state hadrons. In the rest frame of the decay this variable corresponds to the Lorentz factor of the final state $D^{(*)}$ meson. Determinations of $|V_{cb}|$ from experimental measurements of $\bar{B} \to D^{(*)}\ell\bar{\nu}_\ell$ decay rates require precise knowledge of these form factors. Fortunately, lattice QCD results for all relevant form factors, including their recoil dependence, are now available [7–9]. Heavy Quark Symmetry (HQS) [10, 11] predicts that in the infinite mass limit the six form factors collapse into a single one, which is normalized at the "zero recoil point" $w = 1$, the point of maximum momentum transfer to the leptons. Heavy Quark Effective Theory (HQET) provides a framework for obtaining the corrections to the HQS prediction in a systematic expansion in powers of $\Lambda_{\rm QCD}/m_c$ which is discussed in a separate RPP mini-review [3].

76.2.2 $\bar{B} \to D^*\ell\bar{\nu}_\ell$

The decay rate for $\bar{B} \to D^*\ell\bar{\nu}_\ell$, assuming massless leptons, is given by

$$\frac{d\Gamma}{dw}(\bar{B} \to D^*\ell\bar{\nu}_\ell) = \frac{G_F^2 m_B^5}{48\pi^3}|V_{cb}|^2|\eta_{\rm EW}|^2(w^2-1)^{1/2}P(w)|\mathcal{F}(w)|^2, \tag{76.4}$$

where $P(w)$ is a phase space factor,

$$P(w) = r^3(1-r)^2(w+1)^2\left(1 + \frac{4w}{w+1}\frac{1-2rw+r^2}{(1-r)^2}\right), \tag{76.5}$$

with $r = m_{D^*}/m_B$. The decay amplitude $\mathcal{F}(w)$ can be expressed in terms of the form factors which parametrize the vector and axial vector current matrix elements

$$\frac{\langle D^*(v',\epsilon)|\bar{c}\gamma^\mu b|B(v)\rangle}{\sqrt{m_B m_{D^*}}} = h_V(w)\,\varepsilon^{\mu\nu\rho\sigma} v_{B,\nu} v_{D^*,\rho}\epsilon^*_\sigma\,, \tag{76.6}$$

$$\frac{\langle D^*(v',\epsilon)|\bar{c}\gamma^\mu\gamma^5 b|B(v)\rangle}{\sqrt{m_B m_{D^*}}} = ih_{A_1}(w)\,(1+w)\epsilon^{*\mu} - i\left[h_{A_2}(w)v_B^\mu + h_{A_3}(w)v_{D^*}^\mu\right]\epsilon^*\cdot v_B\,, \tag{76.7}$$

and the ratios

$$R_1(w) = \frac{h_V(w)}{h_{A_1}(w)}\,, \quad R_2(w) = \frac{h_{A_3}(w) + r\,h_{A_2}(w)}{h_{A_1}(w)}\,, \tag{76.8}$$

as

$$P(w)|\mathcal{F}(w)|^2 = |h_{A_1}(w)|^2 \times \left\{2\frac{r^2-2rw+1}{(1-r)^2}\left[1+\frac{w-1}{w+1}R_1^2(w)\right] + \left[1+\frac{w-1}{1-r}(1-R_2(w))\right]^2\right\}. \tag{76.9}$$

Note that $\mathcal{F}$ at $w = 1$ is unity by HQS in the infinite-mass limit [12–15]. The effect of assuming massless leptons is typically very small, but for the muon case can be non-negligible in fits to data at high hadronic recoil.

The factor $\eta_{\rm EW} = 1.0066 \pm 0.0050$ accounts for the leading electroweak corrections to the four-fermion operator mediating the semileptonic decay [16], and includes an estimated uncertainty for missing long-distance QED radiative corrections [17]. At present it is not known if these corrections are or are not already included in the experimental analyses, so this needs to be clarified.

The determination of $|V_{cb}|$ requires knowledge of the normalization, where one commonly uses the zero recoil input, $\mathcal{F}(1)$. Theoretical knowledge of the shapes of the form factors provides crucial compatibility checks between theory and experiment, and improves the precision of the determinations. Model-independent shape parametrizations of the from factors make use of analyticity and unitarity constraints and are expressed in terms of the variable

$$z = \frac{\sqrt{w+1}-\sqrt{2}}{\sqrt{w+1}+\sqrt{2}}\,, \tag{76.10}$$

originating from a conformal transformation. In terms of this variable the form factors (generically denoted as F) may be written as [18–22]

$$F(z) = \frac{1}{P_F(z)\phi_F(z)}\sum_{n=0}^{\infty} a_n z^n \tag{76.11}$$

where the sum is bounded, $\sum |a_n|^2 < 1$. Furthermore, the function $P_F(z)$ takes into account the resonances in the $(\bar{c}b)$ system below the $\bar{D}B$ threshold, and the weighting functions $\phi_F(z)$ are derived from the unitarity constraint on the corresponding form factor. The values of z relevant to the decay are $0 \le z \le 0.06$, hence only very few terms are needed in the series in z. Eq. (76.11) will be referred to as the "BGL" expansion.

The Caprini-Lellouch-Neubert (CLN) parametrization [23] yields a simple form

$$h_{A_1}(w) = h_{A_1}(1)\left[1 - 8\rho^2 z + (53\rho^2 - 15)z^2 - (231\rho^2 - 91)z^3\right] \tag{76.12}$$

with the slope ρ and normalization $h_{A_1}(1)$ as the only parameters, albeit at the cost of introducing model dependence. Furthermore, the ratios $R_1(w)$ and $R_2(w)$ are expanded in $w-1$. However, this simple CLN parametrization does not account for higher-order corrections in the $1/m_{c/b}$ expansion, which are now relevant [22, 24–29]. Thus, this report focuses on recent analyses that employ the model-independent BGL expansion. Typical fits include up to three parameters a_n in (76.11) for the different form factors.

Results of the first complete calculation of the $\bar{B} \to D^*\ell\bar{\nu}_\ell$ form factors at non-zero recoil were recently presented by the Fermilab Lattice and MILC collaborations in Ref. [9]. Preliminary results, obtained by the JLQCD collaboration [30], are reasonably consistent. Prior lattice calculations obtained results for only the form factor at the zero-recoil point, $\mathcal{F}(1)$, [17, 31] with a total uncertainty at the (1-2)% level. The average of the two lattice predictions [32] is

$$\mathcal{F}(1) = 0.904 \pm 0.012, \tag{76.13}$$

Non-lattice estimates based on zero-recoil sum rules for the form factor tend to yield lower central values for $\mathcal{F}(1)$ [33–35]. The sum rules indicate that $\mathcal{F}(1) < 0.92$ [33, 34, 36, 37], while an explicit estimate that includes excited state contributions yields $\mathcal{F}(1) \approx 0.86$ [35, 38]. Lattice-QCD form factors at non-zero recoil provide valuable shape constraints, and hence enable more refined $|V_{cb}|$ determinations. However, since they were not available until very recently, most $|V_{cb}|$ determinations in the literature use the value for $\mathcal{F}(1)$ from Eq. (76.13) as the only quantitative lattice input. We discuss these first, before turning to results for $|V_{cb}|$ which employ the lattice-QCD form factors from Ref. [9].

While Light Cone Sum Rules (LCSR) can provide constraints on the form factors at maximum recoil, the underlying systematic errors are not fully quantified. A recent LCSR calculation [39] quotes uncertainties in the $\lesssim 20\%$ range for the $\bar{B} \to D^{(*)}\ell\bar{\nu}_\ell$ form factors at $q^2 = 0$. Dispersive methods [40] can also be used to provide additional constraints on form factors calculated in lattice QCD. Very recent work [41, 42] introduces the dispersive matrix method, which includes additional nonperturbative inputs calculable in lattice QCD from two-point correlation functions. A test of this approach for the $D \to K\ell\nu$ form factors, which can be computed in lattice-QCD over the entire kinematic range, is presented in Ref. [41], while Ref. [42] presents a first lattice-QCD calculation of the needed inputs for the $B \to D^{(*)}$ transitions. The consistency of the dispersive constraints with the form factor calculations still need to be carefully studied, and the dispersive inputs must be calculated with the same care as the form factors themselves.

Many experiments [43–53] have measured the differential decay rate as a function of w, employing a variety of methods: using either B^+ or B^0 decays, with or without B-tagging, and with or without explicit reconstruction of the transition pion from $D^* \to D$ decays. In Ref. [6] the experimental measurements were input to a four-dimensional fit for $\eta_{\rm EW}\mathcal{F}(1)|V_{cb}|$, $\rho^2_{A_1}$ and the form-factor ratios $R_1 \propto A_2/A_1$ and $R_2 \propto V/A_1$. The fit has a p-value of 0.9%, so we scale the uncertainty by a factor $\sqrt{\chi^2/23}$ to give $\eta_{\rm EW}\mathcal{F}(1)\,|V_{cb}| = (35.00 \pm 0.49) \times 10^{-3}$ (CLN).

The leading sources of uncertainty on $\eta_{\rm EW}\mathcal{F}(1)\,|V_{cb}|$ are due to detection efficiencies and $D^{(*)}$ decay branching fractions. Note that the $\bar{B} \to D^*\ell\bar{\nu}_\ell$ form factor in the fit is parameterized using the CLN form, which has the drawbacks discussed previously.

Using the value from Eq. (76.13) for $\mathcal{F}(1)$ and accounting for the electroweak correction gives

$$|V_{cb}| = (38.5 \pm 0.5 \pm 0.6) \times 10^{-3}\ (\bar{B} \to D^*\ell\bar{\nu}_\ell,\ \text{LQCD, CLN}). \tag{76.14}$$

A safer approach is to use the more general BGL form-factor parameterization [19–22, 26]. Two experiments have published analyses with BGL based parametrizations at a given order in the expansion [53, 54]. The Belle analysis [53] is based on an untagged approach in the mode $\bar{B}^0 \to D^{*+}\ell\bar{\nu}_\ell$ and measures 1-d projections in bins of the hadronic recoil w, and angular variables $\cos\theta_\ell$, $\cos\theta_V$, and χ. The BABAR analysis [54] is based on a hadronic tagged sample, and performs a full 4-d unbinned analysis of neutral and charged B decay modes. Only the BGL form factors are fit in this analysis, not the normalization, which is based on the world average $\bar{B} \to D^*\ell\bar{\nu}_\ell$ branching fraction.

At present only Ref. [53] publishes the fully-differential decay rate data and associated covariance matrix. The BGL fit results from Ref. [55], $|V_{cb}| = (38.9 \pm 1.0) \times 10^{-3}$, and Ref. [54], $|V_{cb}| = (38.4 \pm 0.9) \times 10^{-3}$, are consistent with result from the fit with the CLN parametrization, Eq. (76.14). Both studies report fit

results at low order in the three BGL expansion terms, ranging from zero-order to second-order in the Belle analysis, and first order for all terms in the BABAR analysis. Studies of the impact of higher order expansions based on the Belle published decay rate data have been reported in Refs. [27, 28], where it is shown that the fit uncertainty on $|V_{cb}|$ increases by approximately 50% with respect to the results reported at lower order. This is due to larger number of degrees of freedom allowed in the higher order expansions, which are not sufficiently constrained without lattice-QCD inputs at nonzero recoil. Belle II has recently provided first preliminary branching fraction measurements of $\bar{B} \to D^* \ell \bar{\nu}_\ell$ using both tagged and untagged methods [56, 57].

In Ref. [9], BGL expansion fits to the FNAL/MILC lattice QCD form factors show that they are insensitive to truncation effects beyond quadratic order. These form factors were subsequently used in Ref. [9] to extract $|V_{cb}|$ from combined BGL fits to the Belle [53] and synthetic BABAR [54] $\bar{B} \to D^* \ell \bar{\nu}_\ell$ data, yielding $|V_{cb}| = (38.40 \pm 0.74) \times 10^{-3}$. We note that the determination of $|V_{cb}|$ in Ref. [9] applies the Coulomb factor $(1 + \alpha\pi)$ to the Belle data to account for interactions between the charged final states in the neutral B-meson decay. The p-values for the combined (experiment+lattice QCD) BGL fits reported in Ref. [9] are small, reflecting tensions between the data sets. For a fit combining only the Belle data with the lattice-QCD form factors, Ref. [9] quotes $|V_{cb}| = (38.18 \pm 0.82) \times 10^{-3}$, consistent with the result presented in Eq. (76.15), after accounting for the different values of $\eta_{\rm EW}$ used in each result. For this review, the method of Ref. [58] was employed in further fits that include the lattice-QCD inputs at non-zero recoil from FNAL/MILC [9] and from JLQCD (preliminary) [30], yielding consistent results at quadratic order. In summary, we adopt the method of Ref. [58], using the recent FNAL/MILC inputs and only the Belle data (given the lack of availability of binned data from the BABAR measurement [54]). The nominal result for $|V_{cb}|$ is therefore

$$|V_{cb}| = (38.7 \pm 1.0) \times 10^{-3} \ (\bar{B} \to D^* \ell \bar{\nu}_\ell, \ \text{LQCD, BGL}), \quad (76.15)$$

where the uncertainty contains contributions from experimental, lattice QCD, and $\eta_{\rm EW}$ sources. We note that despite the improvements in the experimental data, theoretical inputs, and $|V_{cb}|$ extraction methods, this new exclusive determination of $|V_{cb}|$ is similar in central value to earlier ones, and still in tension with the inclusive determinations discussed in Section 76.2.5 and summarized in Eq. (76.34).

76.2.3 $\bar{B} \to D \ell \bar{\nu}_\ell$

The differential rate for $\bar{B} \to D \ell \bar{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\bar{B} \to D \ell \bar{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 (m_B + m_D)^2 m_D^3 (w^2 - 1)^{3/2} (\eta_{\rm EW} \mathcal{G}(w))^2. \quad (76.16)$$

The form factor is defined in terms of

$$\frac{\langle D(v') | \bar{c} \gamma^\mu b | B(v) \rangle}{\sqrt{m_B m_D}} = h_+(w) \, (v_B + v_D)^\mu + h_-(w) \, (v_B - v_D)^\mu \quad (76.17)$$

and reads

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D} h_-(w), \quad (76.18)$$

where $h_+(1)$ is normalized to unity due to HQS and $h_-(1)$ vanishes in the infinite-mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\left(\frac{m_B - m_D}{m_B + m_D} \right)^2 \frac{\Lambda_{\rm QCD}}{m_c} \right) \quad (76.19)$$

and the corrections to the HQS prediction are of order $\Lambda_{\rm QCD}/m_c$ in contrast to the case of $\mathcal{F}(1)$. The lattice-QCD result for the normalization, $\mathcal{G}(1)$, obtained in Ref. [7] is

$$\mathcal{G}(1) = 1.054 \pm 0.004 \pm 0.008 \, . \quad (76.20)$$

We first turn to $|V_{cb}|$ extractions that rely on only the normalization $\mathcal{G}(1)$ from Eq. (76.20). The most precise measurements of $\bar{B} \to D \ell \bar{\nu}_\ell$ [50, 59, 60] dominate the CLN average [6] value, $\eta_{\rm EW} \mathcal{G}(1) |V_{cb}| = (41.53 \pm 0.98) \times 10^{-3}$. Note that this average corresponds to measurements that are fit to the CLN form factor parameterization; the same concerns expressed above for $\bar{B} \to D^* \ell \bar{\nu}_\ell$ apply here. Using the value from Eq. (76.20) for $\mathcal{G}(1)$ and accounting for the electroweak correction as above gives

$$|V_{cb}| = (39.1 \pm 0.9 \pm 0.4) \times 10^{-3} \ \ (\bar{B} \to D \ell \bar{\nu}_\ell, \ \text{LQCD, CLN}), \quad (76.21)$$

where the first uncertainty is from experiment, and the second combines the lattice QCD uncertainty in Eq. (76.20) with the electroweak correction.

For the $\bar{B} \to D \ell \bar{\nu}_\ell$ modes, theoretical input on the shape of the form factor, especially near $w \sim 1$, is especially beneficial to $|V_{cb}|$ determinations, since experimental measurements of the differential decays rate near zero recoil are affected by the more severe phase space suppression, compared to the D^* case. Hence the best $|V_{cb}|$ determinations from exclusive $\bar{B} \to D \ell \bar{\nu}_\ell$ decays employ lattice-QCD form factors obtained over a range of $w \geq 1$ [7, 8], where Ref. [32] provides a lattice average of the two results. Using the BCL parametrization (z-expansion from Ref. [61]) for the form factors, they can be combined with binned measurements from Belle [60] and BABAR [59]. Only Ref. [60] published the full measurement covariance matrix, while Ref. [59] provides the statistical uncertainty covariance. Nevertheless, Ref. [60] is more precise and dominates the average [32], giving

$$|V_{cb}| = (40.1 \pm 1.0) \times 10^{-3} \ \ (\bar{B} \to D \ell \bar{\nu}_\ell, \ \text{LQCD, BCL}). \quad (76.22)$$

This result is consistent with the value reported in Ref. [62], which is based on the same experimental and lattice inputs.

The $|V_{cb}|$ averages from $\bar{B} \to D^* \ell \bar{\nu}_\ell$ and $\bar{B} \to D \ell \bar{\nu}_\ell$ decays using the BGL (Eq. (76.15)) and BCL (Eq. (76.22)) forms, respectively, are reasonably consistent. The correlations between the lattice uncertainties for $\bar{B} \to D^* \ell \bar{\nu}_\ell$ and $\bar{B} \to D \ell \bar{\nu}_\ell$ are discussed in Ref. [32], and considered to be 100% for the statistical uncertainty component. We assume an experimental uncertainty correlation of order 20% and combine the results of Eq. (76.15) and Eq. (76.22), giving

$$|V_{cb}| = (39.4 \pm 0.8) \times 10^{-3} \quad \text{(exclusive)}. \quad (76.23)$$

76.2.4 $B_s \to D_s^{(*)-} \mu^+ \nu_\mu$

Semileptonic decays of B_s mesons are being studied extensively by the LHCb experiment. On the theory side, lattice QCD calculations of the corresponding form factors can proceed using the same methods and gauge-field ensembles as for B-meson decays. In fact, the presence of a strange spectator quark in the B_s-meson decay amplitudes tends to yield smaller statistical and systematic errors in the lattice computation. Nevertheless, to-date there are still fewer lattice-QCD results for B_s-meson form factors available than for the B-meson case, but this situation is quickly changing. For the case of the $B_s \to D_s$ transition, two lattice QCD calculations of the form factors over a range of recoil momenta have been performed by the HPQCD collaboration, the first on $2 + 1$-flavor gauge field ensembles (generated by the MILC collaboration) using NRQCD b-quarks [63]. The second calculation uses the $2 + 1 + 1$-flavor gauge-field ensembles (also generated by MILC), employing the HISQ action for all valence quarks [64]. The all-HISQ approach avoids the need to compute renormalization factors separately, at the cost of requiring an extrapolation to the physical b-quark mass at the lattice spacings used in Ref. [64]. For the $B_s \to D_s^{*-}$ transition, Ref. [31, 65] provide lattice QCD results for the form factor at zero recoil, where Ref. [65] uses a similar set-up as Ref. [64] and reads

$$\mathcal{F}^{B_s \to D_s^*}(1) = 0.9020(96)_{\rm stat}(90)_{\rm sys} \, . \quad (76.24)$$

A first lattice QCD calculation of the $B_s \to D_s^{*-}$ form factors at non-zero recoil, employing ensembles with with 4 flavors of sea quarks, was recently presented in Ref. [66].

LHCb has recently extracted $|V_{cb}|$ from semileptonic B_s^0 decays [67]. The measurement uses both $B_s^0 \to D_s^- \mu^+ \nu_\mu$ and

$B_s^0 \to D_s^{*-}\mu^+\nu_\mu$ decays. The value of $|V_{cb}|$ is determined from the observed yields of B_s^0 decays normalized to those of B^0 decays after correcting for the relative reconstruction and selection efficiencies. The normalization channels are $B^0 \to D^-\mu^+\nu_\mu$ and $B^0 \to D^{*-}\mu^+\nu_\mu$ decays, where the D^- is reconstructed with the same decay mode of the D_s ($D^-_{(s)} \to [K^+K^-]_\phi\pi^-$). The shape of the form factors are extracted using $p_\perp(D_s)$, which is the component of the D_s^- momentum perpendicular to the B_s^0 flight direction. This variable is correlated with q^2 and the helicity angles in the $B_s^0 \to D_s^{*-}\mu^+\nu_\mu$ decay. For the $B_s \to D_s^-\mu^+\nu_\mu$ decay, for example, $|V_{cb}|$ is related to the measured ratio of signal yields, N_{sig}, and the normalization channel yields, N_{ref}, through the relation

$$\frac{N_{sig}}{N_{ref}} = \xi \frac{f_s}{f_d} \frac{\mathcal{B}(D_s^- \to K^+K^-\pi^-)}{\mathcal{B}(D^- \to K^+K^-\pi^-)} \frac{1}{\mathcal{B}(B^0 \to D^-\mu\nu_\mu)} \tau_s \times \int \frac{d\Gamma(B_s \to D_s\mu\nu_\mu)}{dw} dw \ ,$$

where τ_s is the B_s lifetime, and ξ is the efficiency ratio between the signal and the normalization. The analysis uses the lattice-QCD form factors obtained for $B_s \to D_s^-$ over the full kinematic range in Ref. [64] and the zero-recoil result for the $B_s \to D_s^{*-}$ form factor from Ref. [65]. Fits to both the CLN parameterization and a 5-parameter version of BGL were performed. The result for $|V_{cb}|$, updated with the most recent determination of f_s/f_d and $\mathcal{B}(D_s^- \to K^-K^+\pi^-)$ from Ref. [68], are $|V_{cb}|_{\rm CLN} = (40.8 \pm 0.6 \pm 0.9 \pm 1.1) \times 10^{-3}$, and $|V_{cb}|_{\rm BGL} = (41.7 \pm 0.8 \pm 0.9 \pm 1.1) \times 10^{-3}$, where the first uncertainty is statistical, the second systematic and the third due to the limited knowledge of the external inputs, in particular the constant $f_s/f_d \times \mathcal{B}(D_s^- \to K^+K^-\pi^-)$. The results obtained are consistent with the exclusive determinations of $|V_{cb}|$ using the B^0 and B^+ decays but are not used in the overall average in this review at this stage. These channels are important in the measurement of the ratio $|V_{ub}|/|V_{cb}|$, which cancels out the B_s normalisation uncertainties, discussed in Section 76.5.

76.2.5 $|V_{cb}|$ *from inclusive decays*

Measurements of the total semileptonic branching decay rate, along with moments of the lepton energy and hadronic invariant mass spectra in inclusive semileptonic $b \to c$ transitions, can be used for a precision determination of $|V_{cb}|$. The total semileptonic decay rate can be calculated quite reliably in terms of nonperturbative parameters that can be extracted from the information contained in the moments.

76.2.6 *Inclusive semileptonic rate*

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE) [69,70]. Details can be found in the RPP mini-review on Effective Theories [3].

The OPE result for the total rate can be written schematically (details can be found, *e.g.*, in Ref. [71]) as

$$\begin{aligned}\Gamma =& |V_{cb}|^2 \frac{G_F^2 m_b^5(\mu)}{192\pi^3} |\eta_{\rm EW}|^2 \times \\ & \left[z_0^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_0^{(1)}(r) + \left(\frac{\alpha_s(\mu)}{\pi}\right)^2 z_0^{(2)}(r) + \cdots \right. \\ & + \frac{\mu_\pi^2}{m_b^2}\left(z_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_2^{(1)}(r) + \cdots \right) \\ & + \frac{\mu_G^2}{m_b^2}\left(y_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_2^{(1)}(r) + \cdots \right) \\ & + \frac{\rho_{\rm D}^3}{m_b^3}\left(z_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_3^{(1)}(r) + \cdots \right) \\ & \left. + \frac{\rho_{\rm LS}^3}{m_b^3}\left(y_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_3^{(1)}(r) + \cdots \right) + ... \right] \end{aligned} \quad (76.25)$$

where r is the ratio m_c/m_b and the y_i and z_i are perturbatively calculable Wilson coefficients functions that appear at different orders of the heavy mass expansion.

The parameters μ_π^2, μ_G^2, ρ_D^3 and ρ_{LS}^3 constitute the nonperturbative input into the heavy quark expansion; they correspond to certain matrix elements to be discussed below. In the same way the HQE can be set up for the moments of distributions of charged-lepton energy, hadronic invariant mass and hadronic energy, e.g.

$$\langle E_e^n \rangle_{E_e > E_{\rm cut}} = \int_{E_{\rm cut}}^{E_{\rm max}} \frac{d\Gamma}{dE_e} E_e^n dE_e \Big/ \int_{E_{\rm cut}}^{E_{\rm max}} \frac{d\Gamma}{dE_e} dE_e \ . \quad (76.26)$$

The coefficients of the HQE are known up to order $1/m_b^5$ at tree level [72–75]. The leading term $z_0^{(i)}$ is the parton model, and is known completely through order α_s^2 [76–78] and now also at α_s^3 [79]. The terms of order $\alpha_s^{n+1}\beta_0^n$ (where β_0 is the first coefficient of the QCD β function, $\beta_0 = (33 - 2n_f)/3$) have been included following the BLM procedure [71, 80–83]. Corrections of order $\alpha_s\mu_\pi^2/m_b^2$ have been computed in Ref. [84] and Ref. [85], while the $\alpha_s\mu_G^2/m_b^2$ terms have been calculated in Ref. [86] and Ref. [87], and the $\alpha_s\rho_D^3/m_b^3$ corrections in Ref. [88].

Starting at order $1/m_b^3$ contributions with an infrared sensitivity to the charm mass, m_c, appear [72, 74, 89, 90]. At order $1/m_b^3$ this "intrinsic charm" contribution manifests as a $\log(m_c)$ in the coefficient of the Darwin term ρ_D^3. At higher orders, terms such as $1/m_b^3 \times 1/m_c^2$ and $\alpha_s(m_c)1/m_b^3 \times 1/m_c$ appear, which are comparable in size to the contributions of order $1/m_b^4$.

The HQE parameters are given in terms of forward matrix elements of local operators; the parameters entering the expansion for orders up to $1/m_b^3$ are ($D_\perp^\mu = (g_{\mu\nu} - v_\mu v_\nu)D^\nu$, where $v = p_B/M_B$ is the four-velocity of the B meson)

$$\begin{aligned} \overline{\Lambda} &= M_B - m_b \, , \\ \mu_\pi^2 &= -\langle B|\bar{b}(iD_\perp)^2 b|B\rangle \, , \\ \mu_G^2 &= \langle B|\bar{b}(iD_\perp^\mu)(iD_\perp^\nu)\sigma_{\mu\nu} b|B\rangle \, , \\ \rho_{\rm D}^3 &= \langle B|\bar{b}(iD_{\perp\mu})(ivD)(iD_\perp^\mu) b|B\rangle \, , \\ \rho_{\rm LS}^3 &= \langle B|\bar{b}(iD_\perp^\mu)(ivD)(iD_\perp^\nu)\sigma_{\mu\nu} b|B\rangle . \end{aligned} \quad (76.27)$$

These parameters still depend on the heavy quark mass. Sometimes the infinite mass limits of these parameters $\overline{\Lambda} \to \overline{\Lambda}_{\rm HQET}$, $\mu_\pi^2 \to -\lambda_1$, $\mu_G^2 \to 3\lambda_2$, $\rho_D^3 \to \rho_1$ and $\rho_{LS}^3 \to 3\rho_2$, are used instead. Beyond $1/m^3$ the number of independent HQE parameters starts to proliferate [91]. In general, there are 13 parameters (at tree level) up to order $1/m^4$ and 31 (at tree level) up to order $1/m^5$, not including $\overline{\Lambda}$. The HQE parameters of the orders $1/m_b^4$ and $1/m_b^5$ have been estimated in Ref. [75,92], their impact on the $|V_{cb}|$ determination has been studied in Ref. [93]. However, as pointed out in Ref. [94]one may reduce the number of independent parameters in the HQE by exploiting reparametrization invariance, which is a symmetry of the HQE stemming from Lorentz invariance of QCD. For a subset of observables this allows us to reduce the number of parameters to three up to order $1/m^3$ (ρ_{LS}^3 can be absorbed into μ_G^2 by a re-definition) and to 8 up to order $1/m^4$ [95].

The perturbative QCD expansion for the decay rate does not converge, in general. In addition, the expansion coefficients in the rates and spectra depend strongly on the scheme used for m_b (or equivalently on $\overline{\Lambda}$). It is well known (see eg. [96]) that using the pole mass definition for heavy quark masses leads to particularly badly behaved expansions. This motivates the use of "short-distance" mass definitions, such as the kinetic scheme [33] or the $1S$ scheme [97–99]. Both schemes are well suited for the HQE, since they allow the choice of the renormalization scale $\mu \le m_b$. Furthermore, in both schemes, the masses can be extracted from other observables with sufficient precision, enabling a precise determination of $|V_{cb}|$, despite of the strong quark-mass dependence of the total rate.

The $1S$ scheme eliminates the b quark pole mass by relating it to the perturbative expression for the mass of the $1S$ state of the Υ system. The b quark mass in the $1S$ scheme is half of the perturbatively calculated mass of the $1S$ state of the Υ system. The best determination of the b quark mass in the $1S$ scheme is obtained

from sum rules for $e^+e^- \to b\bar{b}$ [100]. A second alternative is the so-called "kinetic mass" $m_b^{\rm kin}(\mu)$, which enters the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy-quark sum rules [33]. The relation between $m_b^{\rm kin}$ and $m_b^{\overline{MS}}$ is known through three-loop order [101].

Finally, we note that the theoretical description of inclusive decays employed here, is based on the assumption of quark-hadron duality. While there is no evidence of violations of quark-hadron duality, the theoretical uncertainties due to such violations are not well quantified [3].

76.2.7 *Determination of HQE Parameters and $|V_{cb}|$*

Several experiments have measured moments in $\bar{B} \to X_c\ell\bar{\nu}_\ell$ decays [102–110] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum ($0^{\rm th}$-$3^{\rm rd}$) and of the squared hadronic mass spectrum ($0^{\rm th}$-$2^{\rm nd}$) have statistical uncertainties that are roughly equal to their systematic uncertainties. The $3^{\rm rd}$ order hadronic mass spectrum moments have also been measured by some experiments, with relatively large statistical uncertainty. The sets of moments measured within each experiment have strong correlations; their use in a global fit requires fully specified statistical and systematic covariance matrices. Measurements of photon energy moments ($0^{\rm th}$-$2^{\rm nd}$) in $B \to X_s\gamma$ decays [111–115] as a function of the minimum accepted photon energy are also used in some fits; the dominant uncertainties on these measurements are statistical.

Global fits [110, 112, 116–121] to the full set of moments have been performed in the $1S$ and kinetic schemes. The semileptonic moments alone determine a linear combination of m_b and m_c very accurately but leave the orthogonal combination poorly determined (See e.g. [122]); additional input is required to allow a precise determination of m_b. This additional information can come from the radiative $B \to X_s\gamma$ moments (with the caveat that the OPE for $b \to s\gamma$ breaks down beyond leading order in $\Lambda_{\rm QCD}/m_b$), which provide complementary information on m_b and μ_π^2, or from precise determinations of the charm quark mass [32,123]. The values obtained in the kinetic scheme fits [6,120,121] with these two constraints are consistent. Based on the charm quark mass constraint $m_c^{\overline{\rm MS}}(3\,{\rm GeV}) = 0.986 \pm 0.013\,{\rm GeV}$ [124], a fit in the kinetic scheme [6] obtains

$$|V_{cb}| = (42.19 \pm 0.78) \times 10^{-3} \tag{76.28}$$

$$m_b^{\rm kin} = (4.554 \pm 0.018)\,{\rm GeV} \tag{76.29}$$

$$\mu_\pi^2({\rm kin}) = (0.464 \pm 0.076)\,{\rm GeV}^2, \tag{76.30}$$

where the errors include experimental and theoretical uncertainties. Theoretical uncertainties from higher orders in $1/m$ as well as in α_s are estimated and included in performing the fits. Similar values for the parameters are obtained with a variety of assumptions about the theoretical uncertainties and their correlations. The χ^2/dof is well below unity in all fits, which could suggest that the theoretical uncertainties may be overestimated. However, while one could obtain a satisfactory fit with smaller uncertainties, this would result in unrealistically small uncertainties on the extracted HQE parameters, which are used as input to other calculations (e.g. the determination of $|V_{ub}|$). The mass in the $\overline{\rm MS}$ scheme corresponding to Eq. (76.29) is $m_b^{\overline{\rm MS}} = 4.19 \pm 0.04\,{\rm GeV}$, where the uncertainty includes a contribution from the translation between mass schemes; this can be compared to the result quoted in the FLAG review [32], $m_b^{\overline{\rm MS}} = (4.198 \pm 0.012)$ GeV, which provides a non-trivial cross-check.

A fit to the measured moments in the $1S$ scheme [6, 112, 119] gives

$$|V_{cb}| = (41.98 \pm 0.45) \times 10^{-3}, \tag{76.31}$$

$$m_b^{1S} = (4.691 \pm 0.037)\,{\rm GeV}, \tag{76.32}$$

$$\lambda_1(1S) = (-0.362 \pm 0.067)\,{\rm GeV}^2. \tag{76.33}$$

This fit uses moments measurements from semileptonic and radiative decays and constrains the chromomagnetic operator using the B^*-B and D^*-D mass differences, but does not include the constraint on m_c nor all known higher order corrections.

The fits in the two renormalization schemes give consistent results for $|V_{cb}|$ and, after translation to a common renormalization scheme, for m_b and μ_π^2. We take the fit in the kinetic scheme [121], which includes higher-order corrections and results in a more conservative uncertainty, as the inclusive determination of $|V_{cb}|$:

$$|V_{cb}| = (42.2 \pm 0.8) \times 10^{-3}\ \text{(inclusive)}. \tag{76.34}$$

The precision of the global fit results can be further improved by calculating higher-order perturbative corrections to the coefficients of the HQE parameters. Indeed, a very recent analysis presented in Ref. [125] includes calculations of the third-order corrections to the semi-leptonic $b \to c\ell\nu$ decay width [79] and mass relations [101, 126] to obtain a value for $|V_{cb}|$ with smaller total uncertainty than in Eq. (76.34). They obtain $|V_{cb}| = (42.16 \pm 0.51) \times 10^{-3}$, as well as an independent determination of $m_b^{\overline{\rm MS}}$, without direct constraints, $m_b^{\overline{\rm MS}} = 4.210 \pm 0.022){\rm GeV}$. Ultimately measurements of higher order moments and moments of additional variables, such as q^2, will further improve the sensitivity of the fits to higher-order terms in the HQE [95]. The Belle experiment has recently reported new measurements of q^2 moments in inclusive $b \to c\ell\nu$ decays Ref. [127], but they are not yet included in the global fit.

76.3 Determination of $|V_{ub}|$

Summary: Currently the best determinations of $|V_{ub}|$ are from $\bar{B} \to \pi\ell\bar{\nu}_\ell$ decays, where combined fits to theory and experimental data as a function of q^2 provide a precision of about 4%; the uncertainties from experiment and theory are comparable in size. Determinations based on inclusive semileptonic B decays are based on different observables and use different strategies to suppress the $b \to c$ background. Most of the determinations are consistent and provide a precision of about 7%, with comparable contributions to the uncertainty from experiment and theory.

The values obtained from inclusive and exclusive B decay determinations are

$$|V_{ub}| = (4.13 \pm 0.12\ ^{+\ 0.13}_{-\ 0.14} \pm 0.18) \times 10^{-3} \quad \text{(inclusive)}, \tag{76.35}$$

$$|V_{ub}| = (3.70 \pm 0.10 \pm 0.12) \times 10^{-3} \quad \text{(exclusive)}, \tag{76.36}$$

where the last uncertainty on the inclusive result was added by the authors of this review and is discussed below. The exclusive and inclusive determinations are independent, and the dominant uncertainties are on multiplicative factors. The results from the two determinations are compatible to within two standard deviations.

This can be compared to the values derived from $|V_{ub}|/|V_{cb}|$ ratio measurements, described in the next section. Taking the value for this ratio from Eq. (76.56), and $|V_{cb}|$ from Eq. (76.3) we obtain.

$$|V_{ub}| = (3.43 \pm 0.32) \times 10^{-3} \qquad (\mathrm{B_s},\ \Lambda_\mathrm{b}), \tag{76.37}$$

We choose to combine only the direct determinations of $|V_{ub}|$, based on the inclusive and exclusive B measurements. In the combination they are weighted by their relative errors, where the uncertainties are treated as normally distributed. The resulting average has $p(\chi^2) = 15\%$, so we scale the error by $\sqrt{\chi^2/1} = 1.4$ to find

$$|V_{ub}| = (3.82 \pm 0.20) \times 10^{-3} \quad \text{(average)}. \tag{76.38}$$

In a future update we will consider the constraints in the $|V_{ub}|$-$|V_{cb}|$ plane from the direct determinations together with the LHCb $|V_{ub}|/|V_{cb}|$ results. This will require a better understanding of $|V_{ub}|/|V_{cb}|$ extractions across a more complete range in q^2, and with finer binning to compare between theory and experiment.

76.3.1 *$|V_{ub}|$ from inclusive decays*

The theoretical description of inclusive $\bar{B} \to X_u\ell\bar{\nu}_\ell$ decays is based on the Heavy Quark Expansion and leads to a predicted total decay rate with uncertainties below 5% [98, 128]. However, the total decay rate is hard to measure due to the large background from CKM-favored $\bar{B} \to X_c\ell\bar{\nu}_\ell$ transitions, and hence the theoretical methods differ from the $\bar{B} \to X_c\ell\bar{\nu}_\ell$ case. For a calculation of the partial decay rate in regions of phase space where

$\bar{B} \to X_c \ell \bar{\nu}_\ell$ decays are suppressed one cannot use the HQE as for $b \to c$, rather one needs to introduce non-perturbative distribution functions, the "shape functions" (SF) [129, 130]. Their exact form is not known, but its moments can be related to the HQE parameters known e.g from the $b \to c$ case.

The shape functions become important when the light-cone momentum component $P_+ \equiv E_X - |P_X|$ is not large compared to Λ_{QCD}, as is the case near the endpoint of the $\bar{B} \to X_u \ell \bar{\nu}_\ell$ lepton spectrum. Partial rates for $\bar{B} \to X_u \ell \bar{\nu}_\ell$ are predicted and measured in a variety of kinematic regions that differ in their sensitivity to shape-function effects.

At leading order in $1/m_b$ only a single shape function (SF) appears, which is universal for all heavy-to-light transitions [129, 130] and can be extracted in $\bar{B} \to X_s \gamma$ decays. At subleading order in $1/m_b$, several shape functions appear [131], along with small "resolved photon contributions" specific for $\bar{B} \to X_s \gamma$ [132–134], and thus the prescriptions that relate directly the partial rates for $\bar{B} \to X_s \gamma$ and $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays [135–143] are limited to leading order in $1/m_b$.

Existing approaches use parametrizations of the leading SF that respect constraints on the normalization and on the first and second moments, which are given in terms of the HQE parameters $\bar{\Lambda} = M_B - m_b$ and μ_π^2, respectively. The relations between SF moments and the HQE parameters are known to second order in α_s [144]; as a result, measurements of HQE parameters from global fits to $\bar{B} \to X_c \ell \bar{\nu}_\ell$ and $\bar{B} \to X_s \gamma$ moments can be used to constrain the SF moments, as well as to provide accurate values of m_b and other parameters for use in determining $|V_{ub}|$. Flexible parametrizations of the SF using orthogonal basis functions [145] or artificial neural networks [146] allow global fits to inclusive B meson decay data [134] that incorporate the known short-distance contributions and renormalization properties of the SF.

HFLAV performs fits on the basis of several approaches, with varying degrees of model dependence. We will consider here the approaches documented in Ref. [147] (BLNP), Ref. [148] (GGOU) and Ref. [149] (DGE).

The triple differential rate in the variables

$$P_\ell = M_B - 2E_\ell, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (76.39)$$

is

$$\frac{d^3\Gamma}{dP_+\, dP_-\, dP_\ell} = \frac{G_F^2 |V_{ub}|^2}{16\pi^2}(M_B - P_+) \quad (76.40)$$
$$\Big\{ (P_- - P_\ell)(M_B - P_- + P_\ell - P_+)\mathcal{F}_1 + (M_B - P_-)(P_- - P_+)\mathcal{F}_2 + (P_- - P_\ell)(P_\ell - P_+)\mathcal{F}_3 \Big\}.$$

The "structure functions", $\mathcal{F}_i$, can be calculated using factorization theorems that have been proven to subleading order in the $1/m_b$ expansion [150].

The BLNP [147] calculation uses these factorization theorems to write the $\mathcal{F}_i$ terms as functions of perturbatively calculable hard coefficients and jet functions, which are convolved with the (soft) light-cone distribution functions.The calculation of $\mathcal{O}(\alpha_s^2)$ contributions [151, 152] is not yet complete and is not included in the $|V_{ub}|$ determination given below.

The leading order term in the $1/m_b$ expansion of the $\mathcal{F}_i$ terms contains a single non-perturbative function and is calculated to subleading order in α_s, while at subleading order in the $1/m_b$ expansion there are several independent non-perturbative functions that have been calculated only at tree level in the α_s expansion.

A distinct approach (GGOU) [148] uses a hard, Wilsonian cutoff that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite m_b and depend on the light-cone component k_+ of the b quark momentum and on the momentum transfer q^2 to the leptons. These functions include subleading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (76.40). Their k_+ moments can be computed in the OPE.

Going to subleading order in α_s requires the definition of a renormalization scheme for the HQE parameters and for the SF. The relation between the moments of the SF and the forward matrix elements of local operators appearing the HQE is plagued by ultraviolet problems and requires additional renormalization. A scheme for improving this behavior was suggested in Ref. [147] and Ref. [153], which introduce a definition of the quark mass (the so-called shape-function scheme) based on the first moment of the measured $\bar{B} \to X_s \gamma$ photon energy spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

There are various ideas to model the SF, but this requires additional assumptions. One approach (DGE) is the so-called "dressed gluon exponentiation" [149], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large β_0 limit, where β_0 has been defined following Eq. (76.25). Other approaches make even stronger assumptions, such as in Ref. [154], which assumes an analytic behavior for the strong coupling in the infrared to perform an extrapolation of perturbation theory.

In order to reduce sensitivity to SF uncertainties, measurements that use a combination of cuts on the leptonic momentum transfer q^2 and the hadronic invariant mass m_X, as suggested in Ref. [155, 156], have been made. In general, experimental measurements of $\bar{B} \to X_u \ell \bar{\nu}_\ell$ into charm-dominated regions (in order to reduce SF uncertainties) are sensitive to the modeling of $\bar{B} \to X_u \ell \bar{\nu}_\ell$ and $\bar{B} \to X_c \ell \bar{\nu}_\ell$ decays. The measurements quoted below have used a variety of functional forms to parametrize the leading SF; a specific error budget for one determination is quoted in the next section. In no case is the parametrization uncertainty estimated to be more than a 2% on $|V_{ub}|$.

Weak Annihilation [148, 157, 158] (WA) can in principle contribute significantly in the high-q^2 region of $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays. Estimates based on semileptonic D_s decays [90, 155, 156, 158] lead to a $\sim 2\%$ uncertainty on the total $\bar{B} \to X_u \ell \bar{\nu}_\ell$ rate from the $\Upsilon(4S)$. The q^2 spectrum of the WA contribution is not well known, but from the OPE it is expected to contribute predominantly at high q^2. Other theoretical investigations [90, 159, 160], a direct search [161], and $\mathcal{B}(B^0 \to X_u \ell \bar{\nu})/\mathcal{B}(B^+ \to X_u \ell \bar{\nu})$ ratio measurements [162–164] indicate that WA is a small effect, but may become a significant source of uncertainty for $|V_{ub}|$ measurements that accept only a small fraction of the full $\bar{B} \to X_u \ell \bar{\nu}_\ell$ phase space.

76.3.2 *Measurements*

We summarize the measurements used in the determination of $|V_{ub}|$ below. Given the improved precision and more rigorous theoretical interpretation of more recent measurements, determinations [165–168] done with LEP data are not considered in this review.

Inclusive electron momentum measurements [169, 170] reconstruct a single charged electron to determine a partial decay rate for $\bar{B} \to X_u \ell \bar{\nu}_\ell$ near the kinematic endpoint. This results in a selection efficiency of order 50% and only modest sensitivity to the modeling of detector response. The inclusive electron momentum spectrum from $B\bar{B}$ events, after subtraction of the $e^+e^- \to q\bar{q}$ continuum background, is fitted to a model $\bar{B} \to X_u \ell \bar{\nu}_\ell$ spectrum and several components ($D\ell\bar{\nu}_\ell$, $D^*\ell\bar{\nu}_\ell$, ...) of the $\bar{B} \to X_c \ell \bar{\nu}_\ell$ background; the dominant uncertainties are related to this subtraction and modelling. The decay rate can be cleanly extracted for $E_e > 2.3\,\text{GeV}$, but this is deep in the SF region, where theoretical uncertainties are large. More recent measurements have increased the accessed phase phase. The resulting $|V_{ub}|$ values for various E_e cuts are given in Table 76.1.

The most recent BABAR measurement [171] is based on the inclusive electron spectrum and determines the partial branching fraction and $|V_{ub}|$ for $E_e > 0.8\,\text{GeV}$. The analysis shows that the partial branching fraction measurements can have signal model dependence when the kinematic acceptance includes regions dominated by $\bar{B} \to X_c \ell \bar{\nu}_\ell$ background. The model dependence enters primarily through the partial branching fractions, and arises because the signal yield fit has sensitivity to $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays only in regions with good signal to noise.

An untagged "neutrino reconstruction" measurement [172] from

BABAR uses a combination [173] of a high-energy electron with a measurement of the missing momentum vector. This allows S/B~ 0.7 for $E_e > 2.0$ GeV and a $\approx 5\%$ selection efficiency, but at the cost of a smaller accepted phase space for $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays and uncertainties associated with the determination of the missing momentum.

The large samples accumulated at the B factories allow studies in which one B meson is fully reconstructed and the recoiling B decays semileptonically [174–177]. The experiments can fully reconstruct a "tag" B candidate in about 0.5% (0.3%) of B^+B^- ($B^0\bar{B}^0$) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag B and the remaining particles are assigned to the X_u system. The full set of kinematic properties (E_ℓ, m_X, q^2, *etc.*) are available for studying the semileptonically decaying B, making possible selections that accept up to 90% of the full $\bar{B} \to X_u \ell \bar{\nu}_\ell$ rate; however, the sensitivity to $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays is still driven by the regions where $\bar{B} \to X_c \ell \bar{\nu}_\ell$ decays are suppressed. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with additional missing particles, undetected or mis-measured particles from $\bar{B} \to X_c \ell \bar{\nu}_\ell$ decay (e.g., K_L^0 and additional neutrinos) remain an important source of uncertainty.

A new recoil method measurement of partial branching fractions in three phase-space regions, covering about 31% to 86% of the accessible phase space, was performed by Belle [162], where machine learning techniques were used to reduce background levels. The measurement contains substantial decay model updates and supersedes previous measurements from Belle [175,176]. The measurement of the partial branching fraction obtained in the $E_\ell^B > 1$GeV region, the most precise one, is used to obtain $|V_{ub}|$ [162]. Belle also reports preliminary measurements of the background subtracted, and unfolded differential decay spectra in bins of m_X, m_X and q^2, P_+ and E_ℓ [178] for use in global fit analyses. Earlier measurements by BABAR [174] were also performed with cuts on m_X, m_X and q^2, P_+ and E_ℓ using the recoil method. In each case the experimental systematic uncertainties have significant contributions from the modeling of $\bar{B} \to X_u \ell \bar{\nu}_\ell$ and $\bar{B} \to X_c \ell \bar{\nu}_\ell$ decays and from the detector response to charged particles, photons and neutral hadrons. The corresponding $|V_{ub}|$ values are given in Table 76.1.

76.3.3 $|V_{ub}|$ *from inclusive partial rates*

The measured partial rates and theoretical calculations from BLNP, GGOU and DGE described previously are used to determine $|V_{ub}|$ from all measured partial $\bar{B} \to X_u \ell \bar{\nu}_\ell$ rates [6]; selected values are given in Table 76.1. The correlations amongst the multiple BABAR recoil-based measurements [174] are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are small (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments. As an illustration of the relative sizes of the uncertainties entering $|V_{ub}|$ we give the error breakdown for the GGOU average: statistical—1.3%; experimental—1.6%; $\bar{B} \to X_c \ell \bar{\nu}_\ell$ modeling—0.9%; $\bar{B} \to X_u \ell \bar{\nu}_\ell$ modeling—1.7%; HQE parameters (m_b) —1.8%; higher-order corrections—1.5%; q^2 modeling—1.3%; Weak Annihilation—$^{+0.0}_{-1.1}$%; SF parametrization—0.1%.

The averages quoted here are based on the following m_b values: $m_b^{SF} = 4.582 \pm 0.023 \pm 0.018$ GeV for BLNP, $m_b^{\rm kin} = 4.554 \pm 0.018$ GeV for GGOU, and $m_b^{\overline{MS}} = 4.188 \pm 0.043$ GeV for DGE. The $m_b^{\rm kin}$ value is determined in a global fit to moments in the kinetic scheme [6]; this value is translated into m_b^{SF} and $m_b^{\overline{MS}}$ at fixed order in α_s. The second uncertainty quoted on m_b arises from the scheme translation.

Hadronization uncertainties also impact the $|V_{ub}|$ determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (*e.g.* $\bar{B} \to \pi \ell \bar{\nu}_\ell$); this must be added to the simulated $\bar{B} \to X_u \ell \bar{\nu}_\ell$ event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables (q^2, E_ℓ, m_X) averaged over the sample, but these prescriptions are *ad hoc* and ultimately require *in situ* calibration. The resulting uncertainties have been estimated to be $\sim$ 1-2% on $|V_{ub}|$.

All calculations yield compatible $|V_{ub}|$ values and similar error estimates. The arithmetic mean of the values and errors of the HFLAV combinations listed in Table 76.1 is $|V_{ub}| = (4.13 \pm 0.12_{\rm exp}\ ^{+0.13}_{-0.14\ \rm theo}) \times 10^{-3}$, although there is a spread of approximately 10% in the evaluations with the three theoretical models. For reasons discussed below, we assign an additional uncertainty due to model dependence that is not reflected in the HFLAV averages. As highlighted in the BABAR analysis [171], model dependence entering measurement procedures can be sizeable, and is not consistently treated across analyses. Many of the analyses shown in Table 76.1 were based on partial branching fraction measurements determined in a single model (i.e. the one used by that analysis when simulating $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays), although in some cases simulated events were weighted to match the expected spectra in other models and the differences introduced as systematic uncertainties, e.g. Ref. [176]. The $|V_{ub}|$ value quoted by HFLAV for each model are, typically, derived from this unique partial branching fraction combined with another model-specific partial rate calculation. The model dependence in the partial branching fraction is sensitive to how the model predictions compare in the restricted region with good signal-to-noise, not by how they compare when integrated over the full kinematic range used in the fit. Ideally this effect needs to be accounted for by the experiments; the published information is insufficient to determine it. To account for the range in results using the different theoretical models, we take half of the spread of the averages as an additional systematic uncertainty, denoted Δmodel. With this addition, the inclusive $|V_{ub}|$ average is

$$|V_{ub}| = (4.13 \pm 0.12_{\rm exp}\ ^{+0.13}_{-0.14\ \rm theo} \pm 0.18_{\Delta \rm model}) \times 10^{-3} \quad \text{(inclusive)}. \tag{76.41}$$

76.3.4 $|V_{ub}|$ *from exclusive decays*

Exclusive charmless semileptonic decays offer a complementary means of determining $|V_{ub}|$. For the experiments, the specification of the final state provides better background rejection, but the branching fraction to a specific final state is typically only a few percent of that for inclusive decays. For theory, the calculation of the form factors for $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on $\bar{B} \to \pi \ell \bar{\nu}_\ell$, as it is the most promising decay mode for both experiment and theory. Measurements of other exclusive $\bar{B} \to X_u \ell \bar{\nu}_\ell$ decays can be found in Refs. [179–192].

76.3.5 $\bar{B} \to \pi \ell \bar{\nu}_\ell$ *form factor calculations*

The relevant form factors for the decay $\bar{B} \to \pi \ell \bar{\nu}_\ell$ are usually defined as

$$\langle \pi(p_\pi) | V^\mu | B(p_B) \rangle = f_+(q^2) \left[p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \right] + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \tag{76.42}$$

in terms of which the rate becomes (in the limit $m_\ell \to 0$)

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_\pi|^3 |f_+(q^2)|^2, \tag{76.43}$$

where p_π is the pion momentum in the B meson rest frame.

Lattice-QCD calculations of the form factors for the $B \to \pi \ell \bar{\nu}$ and $B_s \to K \ell \bar{\nu}$ transitions are available from the Fermilab/MILC [193, 194], HPQCD [195], and RBC/UKQCD [196] collaborations. The lattice form factors are obtained in the large q^2 region, $q^2_{\rm max} > q^2 \gtrsim 15\,{\rm GeV}^2$ and the calculations differ in actions employed for the b quark. While HPQCD [195] is using lattice-nonrelativistic QCD, the results from Fermilab/MILC [193, 194]and RBC/UKQCD [196] are obtained with relativistic b quark actions based on the Fermilab approach [197]. The results agree within the quoted errors. For the $B \to \pi$

Table 76.1: $|V_{ub}|$ (in units of 10^{-5}) from inclusive $\bar{B} \to X_u \ell \bar{\nu}_\ell$ measurements. The first uncertainty on $|V_{ub}|$ is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are generally listed in order of increasing kinematic acceptance, f_u (0.19 to 0.90), except for the BABAR E_e >0.8 GeV measurement; those below the horizontal bar are based on recoil methods.

form factor $f_+(q^2 = 20\,\mathrm{GeV}^2)$, Ref. [193] quotes uncertainty of 3.4%evaluated at $q^2 = 20\,\mathrm{GeV}^2$, where the leading contribution is due to the chiral-continuum extrapolation fit, which includes statistical and heavy-quark discretization errors.

The extrapolation to small values of q^2 is performed using guidance from analyticity and unitarity. Making use of the heavy-quark limit, stringent constraints on the shape of the form factor can be derived [198], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in the variable

$$z = \frac{\sqrt{t_+ - t_-} - \sqrt{t_+ - q^2}}{\sqrt{t_+ - t_-} + \sqrt{t_+ - q^2}} \,, \tag{76.44}$$

where $t_\pm = (M_B \pm m_\pi)^2$. The use of lattice data in combination with experimental measurements of the differential decay rate provides a stringent constraint on the shape of the form factor in addition to precise determination of $|V_{ub}|$ [199].

LCSR calculations provide estimates for the product $f_B f_+(q^2)$, valid in the region $0 < q^2 \lesssim 12$ GeV. The determination of $f_+(q^2)$ itself requires knowledge of the decay constant f_B, which is usually obtained by replacing f_B by its two-point QCD (SVZ) sum rule [200] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio $(f_B f_+)/(f_B)$. The LCSR for $f_B f_+$ is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite b-quark mass. The resulting expressions comprise a triple expansion: in the twist, t, of the operators near the light-cone, in α_s, and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry. The state-of-the-art calculations include the leading twists two, three and four with full one-loop α_s corrections [201,202] and partial two-loop corrections [203]. Higher-twist contributions have been investigated in Ref. [204] and two-particle higher twist contributions are studied in Ref. [39]. Nevertheless, estimates based on LCSR generally suffer from difficult to quantify systematic uncertainties.

A detailed statistical analysis including the various correlations has been performed in Ref. [205], also including unitarity bounds on the form factor. The results obtained are numerically compatible with the lattice QCD calculations of the form factor. For a determination of V_{ub} one may use the partial rate expressed by the integral

$$\begin{aligned} \Delta\zeta(0, q^2_{max}) &= \frac{G_F^2}{24\pi^3} \int_0^{q^2_{max}} dq^2\, p_\pi^3 |f_+(q^2)|^2 \\ &= \frac{1}{|V_{ub}|^2 \tau_{B_0}} \int_0^{q^2_{max}} dq^2\, \frac{d\mathcal{B}(B \to \pi\ell\nu)}{dq^2} \,, \end{aligned} \tag{76.45}$$

for which the light-cone sum rule gives [205]

$$\Delta\zeta(0, 12\,\mathrm{GeV}^2) = \left(5.25^{+0.68}_{-0.54}\right)\ \mathrm{ps}^{-1}. \tag{76.46}$$

The uncertainty in this integral is about ten percent, which translates to a theoretical uncertainty of about five percent for the determination of V_{ub} with this method.

76.3.6 $\bar{B} \to \pi\ell\bar{\nu}_\ell$ measurements

The $\bar{B} \to \pi\ell\bar{\nu}_\ell$ measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second B meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have better q^2 resolution, high and uniform acceptance and S/B as high as 10, but lower statistical power. The untagged measurements have higher background (S/B < 1) and make slightly more restrictive kinematic cuts, but still provide statistical power precision on the q^2 dependence of the form factor.

CLEO has analyzed $\bar{B} \to \pi\ell\bar{\nu}_\ell$ and $\bar{B} \to \rho\ell\bar{\nu}_\ell$ using an untagged analysis [186–188]. Similar analyses have been done at BABAR [189–192] and Belle [206]. The leading systematic uncertainties in the untagged $\bar{B} \to \pi\ell\bar{\nu}_\ell$ analyses are associated with modeling the missing momentum reconstruction, with background from $\bar{B} \to X_u\ell\bar{\nu}_\ell$ decays and $e^+e^- \to q\bar{q}$ continuum events, and with varying the form factor used to model $\bar{B} \to \rho\ell\bar{\nu}_\ell$ decays.

Analyses [181,207] based on reconstructing a B in the $\bar{D}^{(*)}\ell^+\nu_\ell$ decay mode and looking for a $\bar{B} \to \pi\ell\bar{\nu}_\ell$ or $\bar{B} \to \rho\ell\bar{\nu}_\ell$ decay amongst the remaining particles in the event make use of the fact that the B and $\bar{B}$ are back-to-back in the $\Upsilon(4S)$ frame to construct a discriminant variable that provides a signal-to-noise ratio above unity for all q^2 bins. A related technique was discussed in Ref. [208]. BABAR [207] and Belle [179] have also used their samples of B mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays, resulting in very clean but smaller samples. The dominant systematic uncertainties in the tagged analyses arise from tag calibration.

$|V_{ub}|$ can be obtained from the average $\bar{B} \to \pi\ell\bar{\nu}_\ell$ branching fraction and the measured q^2 spectrum. Fits to the q^2 spectrum using a theoretically motivated parametrization (e.g. "BCL" from

Ref. [61]) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum. The most sensitive method for determining $|V_{ub}|$ from $\bar{B} \to \pi\ell\bar{\nu}_\ell$ decays employs a simultaneous fit [6, 193, 198, 199, 209, 210] to measured experimental partial rates and lattice points versus q^2 (or z) to determine $|V_{ub}|$ and the first few coefficients of the expansion of the form factor in z. We quote the result from Ref. [6], which uses as experimental input an average of the measurements in Refs. [179, 189, 192, 206] and an average [211] of the LQCD input from Ref. [193] and Ref. [196]. The probability of the q^2 measurement average is 6%. The average for the total $B^0 \to \pi^-\ell^+\nu_\ell$ branching fraction is obtained by summing up the partial branching fractions:

$$\mathcal{B}(B^0 \to \pi^-\ell^+\nu_\ell) = (1.50 \pm 0.02_{\rm stat} \pm 0.06_{\rm syst}) \times 10^{-4} \quad (76.47)$$

The corresponding value of $|V_{ub}|$ with this approach is found to be

$$|V_{ub}| = (3.70 \pm 0.10 \pm 0.12\,) \times 10^{-3} \quad \text{(exclusive)}, \qquad (76.48)$$

where the first uncertainty is experimental and the second is from theory. A consistent result for $|V_{ub}|$ was reported in Ref. [32], which uses the same experimental and lattice-QCD inputs. Adding additional constraints using input from LCSR [203] gives [6] $|V_{ub}| = (3.67 \pm 0.09 \pm 0.12\,) \times 10^{-3}$ (exclusive, LQCD+LCSR). Other recent LCSR estimates [212, 213] have been used to obtain consistent results for $|V_{ub}|$, albeit with slightly higher central values. Ref. [213] also presents results for $|V_{ub}|$ from joint fits that exclude some of the experimental data in order to bring the exclusive values into agreement with the inclusive ones.

76.3.7 $\bar{B}_s \to K\ell\bar{\nu}_\ell$

The LHCb experiment have conducted the first observation of the decay $B_s^0 \to K^-\mu^+\nu_\mu$ and the measurements of its branching fraction normalised to the $B_s^0 \to D_s^-\mu^+\nu_\mu$ decays [214]. The measurement has been performed in two bins of q^2, derived using the B_s^0 flight direction and the known B_s^0 mass. The analysis uses a BDT classifier to suppress semileptonic b-hadron background. The results of the partial branching fractions have been translated into measurements of $|V_{ub}|/|V_{cb}|$ using form factor calculations from LCSR for $q^2 < 7$ GeV^2 [215], and a recent LQCD calculation for $q^2 > 7$ GeV^2 [194]. The results are

$$|V_{ub}|/|V_{cb}| = 0.0607 \pm 0.0021 \pm 0.0030, \; q^2 < 7 \text{ GeV}^2 \quad (76.49)$$
$$|V_{ub}|/|V_{cb}| = 0.0946 \pm 0.0041 \pm 0.0068, \; q^2 > 7 \text{ GeV}^2 \quad (76.50)$$

where the first uncertainties include also experimental and external input sources, and the latter are due to the form factor calculations. The sizeable discrepancy between the values of $|V_{ub}|/|V_{cb}|$ for the low and high q^2, requires further investigation. While the experimental measurement has higher purity in the low q^2 region, the theoretical uncertainties in the LCSR results are not fully quantified, unlike the lattice QCD results employed for the high-q^2 region.

76.4 Semileptonic b-baryon decays

Summary: A significant sample of Λ_b^0 baryons is available at the LHCb experiment, and methods have been developed to study their semileptonic decays. Both $\Lambda_b^0 \to p\mu\bar{\nu}$ and $\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu}$ decays have been measured at LHCb, and the ratio of branching fractions to these two decay modes is used to determine the ratio $|V_{ub}/V_{cb}|$.

76.4.1 $\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu}$ and $\Lambda_b^0 \to p\mu\bar{\nu}$

The $\Lambda_b^0 \to \Lambda_c^+$ and $\Lambda_b^0 \to p$ semileptonic transitions are described in terms of six form factors each. The three form factors corresponding to the vector current can be defined as [216]

$$\begin{aligned}\langle F(p',s')|\bar{q}\,\gamma_\mu\, b|\Lambda_b^0(p,s)\rangle = \bar{u}_F(p',s')\Big\{ & f_0(q^2)\,(M_{\Lambda_b^0} - m_F)\,\frac{q_\mu}{q^2} \\ & + f_+(q^2)\,\frac{M_{\Lambda_b^0}+m_F}{s_+}\left(p_\mu + p'_\mu - \frac{q_\mu}{q^2}\,(M^2_{\Lambda_b^0} - m_F^2)\right) \\ & + f_\perp(q^2)\left(\gamma_\mu - \frac{2m_F}{s_+}\,p_\mu - \frac{2M_{\Lambda_b^0}}{s_+}\,p'_\mu\right)\Big\}\, u_{\Lambda_b^0}(p,s)\,,\end{aligned} \quad (76.51)$$

where $F = p$ or Λ_c^+ and where we define $s_\pm = (M_{\Lambda_b^0} \pm m_F)^2 - q^2$. At vanishing momentum transfer, $q^2 \to 0$, the kinematic constraint $f_0(0) = f_+(0)$ holds. The form factors are defined in such a way that they correspond to time-like (scalar), longitudinal and transverse polarization with respect to the momentum-transfer q^μ for f_0, f_+ and $f_\perp$, respectively. Likewise, the expression for the axial-vector current is

$$\begin{aligned}\langle F(p',s')|\bar{q}\,\gamma_\mu\gamma_5\, b|\Lambda_b^0(p,s)\rangle = & \\ - \bar{u}_F(p',s')\gamma_5\Big\{ & g_0(q^2)\,(M_{\Lambda_b^0} + m_F)\,\frac{q_\mu}{q^2} \\ & + g_+(q^2)\,\frac{M_{\Lambda_b^0}-m_F}{s_-}\left(p_\mu + p'_\mu - \frac{q_\mu}{q^2}\,(M^2_{\Lambda_b^0} - m_F^2)\right) \\ & + g_\perp(q^2)\left(\gamma_\mu + \frac{2m_F}{s_-}\,p_\mu - \frac{2M_{\Lambda_b^0}}{s_-}\,p'_\mu\right)\Big\}\, u_{\Lambda_b^0}(p,s)\,,\end{aligned} \quad (76.52)$$

with the kinematic constraint $g_0(0) = g_+(0)$ at $q^2 \to 0$.

In the heavy-quark limit, where both the b and c quarks are treated as heavy, all the form factors reduce to the Isgur Wise function ξ_B for baryons [216]:

$$f_0 = f_+ = f_\perp = g_0 = g_+ = g_\perp = \xi_B \quad (76.53)$$

With a light baryon in the final state, the form factors are related through the heavy quark symmetries of the Λ_b^0, reducing the the number of independent form factors to two. It should be noted that the differential $\Lambda_b^0 \to (p/\Lambda_c^+)\mu\bar{\nu}$ decay rates peak at high q^2, so that the kinematic regions where both lattice QCD calculations and experimental measurements are precise are well matched.

The form factors for Λ_b^0 decays have been studied with lattice QCD [217]. Based on these results the differential rates for both $\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu}$ as well as for $\Lambda_b^0 \to p\mu\bar{\nu}$ can be predicted in the full phase space. In particular, for the experimentally interesting region they find the ratio of decay rates to be [217]

$$\frac{\mathcal{B}(\Lambda_b^0 \to p\mu\bar{\nu})_{q^2>15\text{ GeV}^2}}{\mathcal{B}(\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu})_{q^2>7\text{ GeV}^2}} = (1.471 \pm 0.095 \pm 0.109)\left|\frac{V_{ub}}{V_{cb}}\right|^2 \quad (76.54)$$

where the first uncertainty is statistical and the second, systematic.

76.4.2 *Measurements at LHCb*

The LHCb experiment has measured the branching fractions of the semileptonic decays $\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu}$ and $\Lambda_b^0 \to p\mu\bar{\nu}$, from which they determine $|V_{ub}|/|V_{cb}|$. This is the first such determination at a hadron collider, the first to use a b baryon decay, and the first observation of $\Lambda_b^0 \to p\mu\bar{\nu}$. Excellent vertex resolution allows the $p\mu$ and production vertices to be separated, which permits the calculation of the transverse momentum $p_\perp$ of the $p\mu$ pair relative to the Λ_b^0 flight direction. The corrected mass, $m_{\rm corr} = \sqrt{p_\perp^2 + m_{p\mu}^2} + p_\perp$, peaks at the Λ_b^0 mass for signal decays and provides good discrimination against background combinations. The topologically similar decay $\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu}$ is also measured, which eliminates the need to know the production cross-section or absolute efficiencies. Using vertex and Λ_b^0 mass constraints, q^2 can be determined up to a two-fold ambiguity. The LHCb analysis requires both solutions to be in the high q^2 region to minimise contamination from the low q^2 region. Their result [218],

rescaled [6] to take into account the recent branching fraction measurement [219] $\mathcal{B}(\Lambda_c^+ \to pK^-\pi^+) = (6.28 \pm 0.32)\%$, is

$$\frac{\mathcal{B}(\Lambda_b^0 \to p\mu\bar{\nu})_{q^2>15\mathrm{GeV}^2}}{\mathcal{B}(\Lambda_b^0 \to \Lambda_c^+\mu\bar{\nu})_{q^2>7\mathrm{GeV}^2}} = (0.92 \pm 0.04 \pm 0.07) \times 10^{-2} \quad . \tag{76.55}$$

The largest systematic uncertainty is from the measured $\mathcal{B}(\Lambda_c^+ \to pK^-\pi^+)$; uncertainties due to trigger, tracking and the Λ_c^+ selection efficiency are each about 3%.

A recent LHCb analysis [220] measures the normalized q^2 spectrum and finds good agreement with the shape calculated with lattice QCD [217].

The decay rate for $\Lambda_b^0 \to p\mu\bar{\nu}$ peaks at high q^2 where the calculation of the associated form factors using lattice QCD is under good control. Using the measured ratio from Eq. (76.55) along with the calculated ratio from Ref. [217] (see Eq. (76.54)) results in [6]

$$|V_{ub}|/|V_{cb}| = 0.079 \pm 0.004 \pm 0.004(\Lambda_b). \tag{76.56}$$

where the first uncertainty is experimental and the second is from the LQCD calculation.

76.5 The ratio $|V_{ub}|/|V_{cb}|$

The ratio of matrix elements, $|V_{ub}|/|V_{cb}|$, is often required when testing the compatibility of a set of measurements with theoretical predictions. It can be determined from the ratio of branching fractions measured by the LHCb experiment, quoted in the previous sections. It can also be calculated based on the $|V_{ub}|$ and $|V_{cb}|$ values quoted earlier in this review.

The average of the LHCb results extracted at high q^2 from B_s and Λ_b decays, taken to be uncorrelated, is

$$|V_{ub}|/|V_{cb}| = 0.084 \pm 0.007 \quad (\Lambda_b,\ B_s), \tag{76.57}$$

where the uncertainty has been scaled by a factor $\sqrt{\chi^2/1} = 1.6$.

Given the similarities in the theoretical frameworks used for charmed and charmless decays, we choose to quote separate ratios of $|V_{ub}|/|V_{cb}|$ for inclusive and exclusive B decays, as discussed earlier:

$$|V_{ub}|/|V_{cb}| = 0.098 \pm 0.006 \quad \text{(inclusive)}, \tag{76.58}$$

$$|V_{ub}|/|V_{cb}| = 0.094 \pm 0.005 \quad \text{(exclusive)}. \tag{76.59}$$

The respective determinations of $|V_{ub}|$ and $|V_{cb}|$ are taken to be uncorrelated in the ratio, although there could be some small cancellations of the uncertainties in both the experimental and the theoretical input. We average the B decay values, along with the B_s and baryonic result in Eq. (76.57), weighting by relative errors.The average has $p(\chi^2) = 4\%$, so we scale the uncertainty by a factor $\sqrt{\chi^2/2} = 1.8$ to find

$$|V_{ub}|/|V_{cb}| = 0.091 \pm 0.005 \quad \text{(average)}. \tag{76.60}$$

76.6 Semitauonic decays

Summary: Semileptonic decays to third-generation leptons provide sensitivity to non-Standard Model amplitudes, such as from a charged Higgs boson [221–224] and from leptoquarks [225–231]. The ratios of branching fractions of semileptonic decays involving tau leptons to those involving $\ell = e/\mu$, $R(D^{(*)}) \equiv \mathcal{B}(\bar{B} \to D^{(*)}\tau\bar{\nu}_\tau)/\mathcal{B}(\bar{B} \to D^{(*)}\ell\bar{\nu}_\ell)$, are predicted with good precision and consistency in the Standard Model [7–9, 24, 25, 27, 62], using a variety of different strategies. Because this ratio is independent of $|V_{cb}|$, it can, in principle, be computed entirely from within the Standard Model, without using experimental decay rate data. For example, in Ref. [7,9] the lattice-QCD only ratios are obtained as:

$$R(D)^{\mathrm{LQCD,FNAL-MILC}} = 0.284 \pm 0.014 \ ,$$
$$R(D^*)^{\mathrm{LQCD,FNAL-MILC}} = 0.265 \pm 0.013 \ . \tag{76.61}$$

Without constraints from experimental data at large recoil, such SM-theory only evaluations tend to be less precise than those obtained from joint fits that employ experimental data as well as Standard-Model theory inputs (lattice-QCD form factors, HQET constraints, etc.). Here we use an average of Ref. [25,62] for $R(D)$ and Ref. [9] for $R(D^*)$, where the uncertainty on $R(D^*)$ is scaled by $\sqrt{\chi^2/1} = 1.2$:

$$R(D)^{\mathrm{SM+Exp}} = 0.299 \pm 0.003 \ ,$$
$$R(D^*)^{\mathrm{LQCD+Exp}} = 0.2483 \pm 0.0016 \ . \tag{76.62}$$

Other Standard-Model predictions for $R(D^{(*)})$ [24, 25, 27, 62, 232,233] using various combinations of experimental data, lattice-QCD form factor inputs, HQET constraints, and LCSR estimates are consistent with the values quoted above. In the case of $R(D^*)$, these predictions have larger uncertainties than the result quoted in Eq. (76.62), as non-zero lattice-QCD form factors for $B \to D^*$ were not yet available.

Measurements [234–242] of these ratios yield higher values; averaging B-tagged measurements of $R(D)$ and $R(D^*)$ at the $\Upsilon(4S)$ and the LHCb measurements of $R(D^*)$ yields [243]

$$R(D)^{\mathrm{meas}} = 0.339 \pm 0.026 \pm 0.014 \ ,$$
$$R(D^*)^{\mathrm{meas}} = 0.295 \pm 0.010 \pm 0.010 \ , \tag{76.63}$$

with a linear correlation of -0.38. These values exceed the Standard Model predictions of Eq. (76.62) by 1.4σ and 3.3σ, respectively. Not surprisingly, the tensions with respect to the lattice-QCD only prediction of Eq. (76.61) are less significant, at 1.4σ for $R(D)$ and 1.6σ for $R(D^*)$. A variety of new physics models have been proposed to explain this excess, see eg. Ref. [221–228] and recent reviews in Ref. [244–246].

Most models proposed to explain the semitauonic decay excesses tend to, but not always, have very little impact on semileptonic decays involving muons or electrons, so they do not significantly modify the $|V_{ub}|$ or $|V_{cb}|$ determinations discussed previously in this review. Lepton flavor universality in the ratio of electron and muon modes has been confirmed in direct ratio measurements from Belle: $\mathcal{B}(\bar{B} \to D^* e\bar{\nu}_e)/\mathcal{B}(\bar{B} \to D^*\mu\bar{\nu}_\mu) = 1.01 \pm 0.03$ [53] and $\Delta\mathcal{B}(B \to X_u e^-\bar{\nu}_e)/\Delta\mathcal{B}(B \to X_u\mu^-\bar{\nu}_\mu) = 0.97 \pm 0.10$ [162]. The uncertainty is dominated by lepton identification uncertainties that do not cancel in the ratio.

76.6.1 *Sensitivity of $\bar{B} \to D^{(*)}\tau\bar{\nu}_\tau$ to additional amplitudes*

In addition to the helicity amplitudes present for decays to $e\bar{\nu}_e$ and $\mu\bar{\nu}_\mu$, decays proceeding through $\tau\bar{\nu}_\tau$ include a scalar amplitude H_s. The differential decay rate is given by [247]

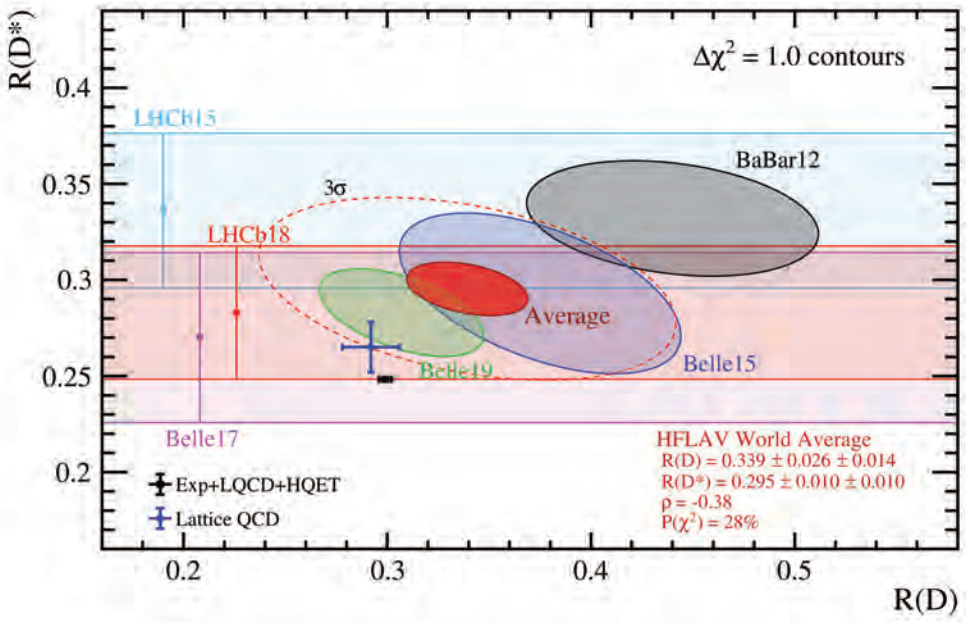
$$\frac{d\Gamma}{dq^2} = \frac{G_F^2\,|V_{cb}|^2\,|\mathbf{p}^*_{D^{(*)}}|q^2}{96\pi^3 m_B^2}\left(1 - \frac{m_\tau^2}{q^2}\right)^2 \left[(|H_+|^2 + |H_-|^2 + |H_0|^2)\left(1 + \frac{m_\tau^2}{2q^2}\right) + \frac{3m_\tau^2}{2q^2}|H_s|^2\right], \tag{76.64}$$

where $|\mathbf{p}^*_{D^{(*)}}|$ is the 3-momentum of the $D^{(*)}$ in the $\bar{B}$ rest frame and the helicity amplitudes H depend on the four-momentum transfer q^2. All four helicity amplitudes contribute to $\bar{B} \to D^*\tau\bar{\nu}_\tau$, while only H_0 and H_s contribute to $\bar{B} \to D\tau\bar{\nu}_\tau$; as a result, new physics contributions can produce larger effects in the latter mode. Semi-leptonic B decays into a τ lepton provide a stringent test of the two-Higgs doublet model of type II (2HDMII), i.e. where the two Higgs doublets couple separately to up- and down-type quarks. The distinct feature of the 2HDMII is that the contributions of the charged scalars scale as $m_\tau^2/m_{H^+}^2$, since the couplings to the charged Higgs particles are proportional to the mass of the lepton. As a consequence, one may expect visible effects in decays into a τ, but only small effects for decays into e and μ. The present data disfavors the 2HDMII, see below.

76.6.2 *Measurement of $R(D^{(*)})$*

$\bar{B} \to D^{(*)}\tau\bar{\nu}_\tau$ decays have been studied at the $\Upsilon(4S)$ resonance and in pp collisions. At the $\Upsilon(4S)$, the majority of experimental measurements are based on signatures that consist of a D or D^* meson, an electron or muon (denoted here by ℓ) from the decay $\tau \to \ell\nu_\tau\bar{\nu}_\ell$, a fully-reconstructed decay of the second B meson in

Figure 76.1: Measurements of $R(D)$ and $R(D^*)$ and their two-dimensional average compared with the average predictions for $R(D)$ and $R(D^*)$. Contours correspond to $\Delta\chi^2 = 1$ *i.e.*, 68% CL for the bands and 39% CL for the ellipses. The average of the Lattice QCD and Experiment-Lattice QCD-HQET predictions and the experimental average deviate from each other by 2.0σ and 4.0σ respectively. The dashed ellipse corresponds to a 3σ contour of the experiment average (99.73% CL).



the event, and multiple missing neutrinos. One analysis reconstructs the τ in a hadronic mode. The analyses that use hadronic B tags separate signal decays from $\bar{B} \to D^{(*)}\ell\bar{\nu}_\ell$ decays using the lepton momentum and the measured missing mass squared; decays with only a single missing neutrino peak sharply at zero in this variable, while the signal is spread out to positive values. When a semileptonic B tag is used, the discrimination between signal and $\bar{B} \to D^{(*)}\ell\bar{\nu}_\ell$ decays comes from the calorimeter energy that is not associated with any particle used in the reconstruction of the B meson candidates, the measured missing mass squared and the cosine of the angle between the $D^*\ell$ system and its parent B meson, which is calculated under the assumption that only one particle (a neutrino) is missing. In both these approaches, background from $\bar{B} \to D^{**}\ell\bar{\nu}_\ell$ decays with one or more unreconstructed particles is challenging to separate from signal, as is background from $\bar{B} \to D^{(*)}H_{\bar{c}}X$ (where $H_{\bar{c}}$ is a hadron containing a $\bar{c}$ quark) decays. The leading sources of systematic uncertainty are due to the limited size of simulation samples used in constructing the PDFs, the composition of the D^{**} states, efficiency corrections, and cross-feed (swapping soft particles between the signal and tag B).

The most recent measurement from Belle [240] uses semileptonic B tags and leptonic τ decays to simultaneously measure $R(D^*)$ and $R(D)$. The measurement provides the single most precise determination of these ratios, combining results from charged and neutral B decays, and is compatible with the Standard Model expectation to approximately 1σ.

In addition to the ratio measurements, the Belle experiment has performed polarization measurements of the τ [239] and D^* [248] respectively. The τ polarization measurement uses hadronic B tags and τ^- decays to $\pi^-\nu_\tau$ or $\rho^-\nu_\tau$. The main discriminant variables are the measured missing mass squared and the unassociated calorimeter energy. This measurement provides the first determination of the τ polarization in the $\bar{B} \to D^*\tau\bar{\nu}_\tau$ decay, $\mathcal{P}_\tau(D^*) = -0.38 \pm 0.51\ ^{+0.21}_{-0.16}$, compatible with the Standard Model expectation [27], $\mathcal{P}_\tau(D^*) = -0.476^{+0.037}_{-0.034}$.

The main uncertainties on the $R(D^*)$ measurement come from the composition of the hadronic B background and from modeling of semileptonic B decays and mis-reconstructed D^* mesons. The D^* polarization measurement uses an inclusive tag approach based on Refs. [249, 250], and reconstructs the τ decays in $\ell\nu_\tau\bar{\nu}_\ell$ and $\pi^+\bar{\nu}_\tau$ channels. The main discriminant variables are $X_{\rm miss}$, a quantity that approximates missing mass but does not depend on tag B reconstruction, the visible energy of the event, and the beam-energy constrained mass, $M_{\rm bc}$, of the inclusively reconstructed tag side B. This measurement provides the first determination of the D^* longitudinal polarization fraction in the $\bar{B} \to D^*\tau\bar{\nu}_\tau$ decay, $\mathcal{F}_L(D^*) = -0.38 \pm 0.60\ ^{+0.08}_{-0.04}$, compatible with the Standard Model expectation [251] within 1.7σ.

The LHCb experiment has studied the decay $\bar{B} \to D^{*+}\tau\bar{\nu}_\tau$ with $D^{*+} \to D^0\pi^+$, $D^0 \to K^-\pi^+$ and $\tau \to \mu\nu_\tau\bar{\nu}_\mu$ in pp collisions. Their analysis [241] takes advantage of the measurable flight lengths of b and c hadrons and τ leptons. A multivariate discriminant is used to select decays where no additional charged particles are consistent with coming from the signal decay vertices. The separation between the primary and B decay vertices is used to calculate the momentum of the B decay products transverse to the B flight direction. The longitudinal component of the B momentum can be estimated based on the visible decay products; this allows a determination of the B rest frame, with modest resolution, and enables the calculation of the same discrimination variables available at the e^+e^- B factories. The (rest frame) muon energy, missing mass-squared and q^2 are used in a 3-d fit. The most recent LHCb result [253] on $R(D^*)$ uses three-prong τ decays that take advantage of their excellent vertex resolution to isolate the τ decay from hadronic background. A 3-d fit is performed to determine the signal yield, based on the τ-ν_τ pair q^2, the τ lifetime, as well as a boosted decision tree classifier based on isolation, invariant mass and flight distance information. The leading sources of systematic uncertainty are due to the size of the simulation sample used in constructing the fit templates, uncertainties in modelling the background from hadronic $\bar{B} \to D^{(*)}H_{\bar{c}}X$ decays, as well as reconstruction and trigger effects. The result is normalized to $B^0 \to D^{*-}\pi^+\pi^-\pi^+$ and found to be 1σ from the Standard Model expectation (using the expectation value quoted here). An analogous measurement of $B_c \to J/\psi\tau\bar{\nu}_\tau$ was performed by the LHCb measurement [254], in

Table 76.2: Measurements of $R(D)$ and $R(D^*)$, their correlations, ρ, and the combined averages [6].

		$R(D) \times 10^2$	$R(D^*) \times 10^2$	ρ
BABAR [235, 236]	B^0, B^+	$44.0 \pm 5.8 \pm 4.2$	$33.2 \pm 2.4 \pm 1.8$	-0.27
Belle [237]	B^0, B^+	$37.5 \pm 6.4 \pm 2.6$	$29.3 \pm 3.8 \pm 1.5$	-0.49
Belle [239, 252]	B^0, B^+		$27.0 \pm 3.5 \,^{+\,2.8}_{-\,2.5}$	
Belle [240]	B^0, B^+	$30.7 \pm 3.7 \pm 1.6$	$28.3 \pm 1.8 \pm 1.4$	-0.51
LHCb [241]	B^0		$33.6 \pm 2.7 \pm 3.0$	
LHCb [253]	B^0		$28.3 \pm 1.9 \pm 2.9$	
Average	B^0, B^+	$33.9 \pm 2.6 \pm 1.4$	$29.5 \pm 1.0 \pm 1.0$	-0.38

leptonic τ decays. The result, $R(J/\psi) = 0.71 \pm 0.17 \pm 0.18$, while relatively high is compatible to within 2σ of a recent Standard Model evaluation [255] based on a latttice-QCD calculation [256] of the form factors. Systematic uncertainties are dominated by form factors, as B_c decays are relatively unexplored.

Measurements from BABAR [234–236], Belle [237–240] and LHCb [241, 253] result in values for $R(D)$ and $R(D^*)$ that exceed Standard Model predictions. Table 76.2 lists these values and their average. The simultaneous measurements of $R(D)$ and $R(D^*)$ have linear correlation coefficients of -0.27 (BABAR [235, 236]), -0.49 (Belle hadronic tag [237]) and -0.51 (Belle semileptonic tag [240]); the $R(D)$ and $R(D^*)$ averages have a correlation of -0.38. Two early untagged Belle measurements [249, 250] are subject to larger systematic uncertainties, with a breakdown of the respective contributions that is inconsistent with the more recent determinations, hence they cannot be reliably combined in the average. All three experiments assume the Standard Model kinematic distributions for $\bar{B} \to D^{(*)}\tau\bar{\nu}_\tau$ in their determinations of the branching fraction ratios.

The measurement combination in the $R(D) - R(D^*)$ plane is shown in Fig. 76.1, compared with the predictions in Eq. (76.61) (LQCD) and Eq. (76.62) (Experiment+LQCD+HQET). The measurement combination is based on Ref. [6]. The tension between the Standard Model prediction in Eq. (76.62) and the measurements is at the level of 1.4σ ($R(D)$) and 3.3σ ($R(D^*)$); if one considers these deviations together the significance is 4.0σ. This motivates speculation on possible new physics contributions. The measurements reported in Refs. [240, 252, 253] resulted in reduced tensions with the Standard-Model predictions in recent editions of the RPP. The main change in this edition is the availability of lattice-QCD form factors at nonzero recoil, which improves the theory uncertainty on $R(D^*)$ and brings the discrepancy to the level reported in earlier editions. There is some tension in the combination coming from the BABAR measurement, the only measurement to claim a deviation from the Standard Model of more than 3σ, although the $p-$value of the full combination is an acceptable 28%.

The current discussion of $R(D)$ and $R(D^*)$ may be embedded in the theoretical analysis of the other anomalies that have been observed in semileptonic FCNC ($b \to s\ell\ell$) transitions. More sophisticated approaches fit the data to a general effective Hamiltonian. Matching this effective Hamiltonian to simplified models, the current situation of the anomalies seems to be compatible with scenarios with an additional Z' or a leptoquark scenario, see eg. [225–231].

76.7 Conclusion

The study of semileptonic B meson decays continues to be an active area for both theory and experiment. The application of HQE calculations to inclusive decays is well established, and fits to moments of $\bar{B} \to X_c\ell\bar{\nu}_\ell$ decays provide precise values for $|V_{cb}|$ and, in conjunction with input on m_c or from $B \to X_s\gamma$ decays, provide precise and consistent values for m_b. Recent developments will make use of more types of moments and better theoretical inputs to constrain higher order effects. Further into the future, new nonperturbative methods to compute inclusive decay rates, for example, in lattice QCD [257], may provide interesting new insights.

The determination of $|V_{ub}|$ from inclusive $\bar{B} \to X_u\ell\bar{\nu}_\ell$ decays is based on multiple calculational approaches and independent measurements over a variety of kinematic regions, all of which provide consistent results. Further progress in this area is possible, but will require better theoretical control over higher-order terms, improved experimental knowledge of the $\bar{B} \to X_c\ell\bar{\nu}_\ell$ background and improvements to the modeling of the $\bar{B} \to X_u\ell\bar{\nu}_\ell$ signal distributions.

In both $b \to u$ and $b \to c$ exclusive channels there has been significant recent progress in lattice-QCD calculations, resulting in improved precision on both $|V_{ub}|$ and $|V_{cb}|$. These calculations now provide information on the form factors well away from the high q^2 region, allowing better use of experimental data. For $|V_{cb}|$ recent measurements have provided binned data enabling model-independent fits.

The values from the inclusive and exclusive determinations of $|V_{cb}|$ and $|V_{ub}|$ are only marginally consistent. This is a long-standing puzzle, which the recent improvements have, unfortunately, not yet resolved. The measurement of $|V_{ub}|/|V_{cb}|$ from LHCb based on Λ_b^0 and B_s decays also do not yet simplify the picture.

Both $|V_{cb}|$ and $|V_{ub}|$ are indispensable inputs into unitarity triangle fits. In particular, knowing $|V_{ub}|$ with good precision allows a test of CKM unitarity in a most direct way, by comparing the length of the $|V_{ub}|$ side of the unitarity triangle with the measurement of $\sin(2\beta)$. This comparison of a "tree" process ($b \to u$) with a "loop-induced" process ($B^0 - \bar{B}^0$ mixing) provides sensitivity to possible contributions from new physics.

The observation of semileptonic decays into τ leptons has opened a new window to the physics of the third generation. The measurements indicate a tension between the data and Standard-Model predictions, which could be a hint for new physics, manifesting itself as a violation of lepton universality beyond the Standard-Model couplings to the Higgs. It should be noted that none of the most recent measurements alone claim discovery of a deviation from the Standard Model. Combining the data of the semitauonic decays with the anomalies observed in the FCNC $b \to s\ell\ell$ transitions allows an interpretation in terms of additional Z' or in terms of additional leptoquarks, but the current data does not allow us to draw a definite conclusion.

The authors would like to acknowledge helpful input from D. Ferlewicz, P. Gambino, S. Hashimoto, Z. Ligeti, M. Rotondo, C. Schwanda, and A. Vaquero.

77. Determination of CKM angles from B hadrons

Revised February 2022 by T. Gershon (Warwick U.), M. Kenzie (Warwick U.) and K. Trabelsi (U. Paris-Saclay, IJCLab).

77.1 Introduction

The Cabibbo–Kobayashi–Maskawa (CKM) description of quark mixing [1,2] leads to a number of triangle relations between pairs of CKM matrix elements. One of these,

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0 \,, \tag{77.1}$$

is of particular interest since (i) all its terms are of comparable magnitude, and (ii) its properties can be measured through studies of oscillations and decays of B mesons. As the area of this unitary triangle is a measure of the amount of CP violation in the Standard Model [3], it is of particular interest to determine the values of its angles and to test the consistency of the CKM paradigm with the experimental measurements. The angles are defined as

$$\begin{aligned} \alpha &= \arg\left[-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right] \,, \qquad \beta = \arg\left[-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right] \,, \\ \gamma &= \arg\left[-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*}\right] \,, \end{aligned} \tag{77.2}$$

with an alternative notation $(\phi_2, \phi_1, \phi_3) \equiv (\alpha, \beta, \gamma)$ also widely used in the literature.

In this mini-review, the most precise methods to determine the CKM angles are described, with a particular focus on nontrivial aspects of the combination of results. More detailed discussions of these points can be found in Ref. [4]. A similar mini-review on the side of the unitarity triangle adjacent to the angle γ can be found in Ref. [5]. A detailed overview of the CKM quark-mixing matrix is given in Ref. [6] while CP violation in the quark sector is discussed in Ref. [7].

77.2 β

The relative weak (*i.e.* CP-violating) phase between the amplitude for any CKM-favoured B^0 meson decay to a CP eigenstate and that for the decay following B^0–$\overline{B}^0$ oscillation is twice the angle β. The decay-time-dependent CP asymmetry can be expressed as

$$\mathcal{A}_{f_{CP}}(t) \equiv \frac{d\Gamma/dt\left[\overline{B}^0_{\rm phys}(t) \to f_{CP}\right] - d\Gamma/dt\left[B^0_{\rm phys}(t) \to f_{CP}\right]}{d\Gamma/dt\left[\overline{B}^0_{\rm phys}(t) \to f_{CP}\right] + d\Gamma/dt\left[B^0_{\rm phys}(t) \to f_{CP}\right]} \,, \tag{77.3a}$$

$$= S_f \sin(\Delta m t) - C_f \cos(\Delta m t) \,, \tag{77.3b}$$

where the notation $B^0_{\rm phys}(t)$ ($\overline{B}^0_{\rm phys}(t)$) denotes a neutral B meson that decays at time t into the final state f_{CP}, and is known ("tagged") at time $t = 0$ to have flavour content corresponding to B^0 ($\overline{B}^0$). In Eq. (77.3b), Δm denotes the mass difference between the two physical eigenstates of the B^0–$\overline{B}^0$ system, while the corresponding decay-width difference is assumed to be negligible [8]; moreover CPT symmetry and the absence of CP violation in B^0–$\overline{B}^0$ mixing is assumed throughout this mini-review.

In the general case, one can write

$$S_f \equiv \frac{2\mathcal{I}m(\lambda_f)}{1+\left|\lambda_f\right|^2} \qquad \text{and} \qquad C_f \equiv \frac{1-\left|\lambda_f\right|^2}{1+\left|\lambda_f\right|^2} \,, \tag{77.4}$$

where the parameter $\lambda_f = \frac{q}{p}\frac{\overline{A}_f}{A_f}$ is defined in terms of p and q, which define the flavour content of the mass eigenstates of the B^0–$\overline{B}^0$ system [8], and the amplitudes $\overline{A}_f$ (A_f) for a $\overline{B}^0$ (B^0) decay to the final state f_{CP}. In the limit that the decay amplitude is dominated by a CKM-favoured transition, as is the case for $B^0 \to J/\psi K^0_{\rm S}$ decays, one obtains simple relations: $S_f = -\eta_{CP}\sin(2\beta)$ and $C_f = 0$, where η_{CP} is the CP eigenvalue of the final state [9,10]. This method has been pursued intensively by experiments. The current world averages, combining results for several charmonium-kaon final states but dominated by results on $B^0 \to J/\psi K^0_{\rm S}$ (CP odd) and $B^0 \to J/\psi K^0_{\rm L}$ (CP even), are [4]

$$-\eta_{CP}S_f = 0.699 \pm 0.017 \,, \qquad C_f = -0.005 \pm 0.015 \,. \tag{77.5}$$

Despite the large number of signal events in the data, the dominant uncertainties are still statistical. One important source of potential systematic correlation between results from different experiments is that due to "tag-side interference" [11], which is common to measurements exploiting production through the $e^+e^- \to \Upsilon(4S) \to B^0\overline{B}^0$ process, including the latest results from BaBar [12] and Belle [13]. It does not, however, affect the results from LHCb [14] that have comparable statistical sensitivity. Another common source of systematic uncertainty is due to knowledge of the value of Δm, but since this quantity has been measured precisely [8] the effect remains small.

The interpretation of the value of $-\eta_{CP}S_f$ from Eq. (77.5) as $\sin(2\beta)$ assumes negligible contributions from subleading amplitudes with a different weak phase to that of the tree diagram (*i.e.* to that of the CKM matrix elements $V_{cb}V_{cs}^*$). This potential additional contribution is often referred to as "penguin pollution". All existing data, including the value of C_f in Eq. (77.5), as well as several explicit calculations [15–18], are consistent with penguin pollution in B^0 meson decays to charmonium-kaon decays being negligible at the current level of precision. Therefore, the value of $-\eta_{CP}S_f$ is generally converted to $\sin(2\beta)$ without any correction or additional uncertainty being assigned due to this assumption. This gives [4]

$$\beta = (22.2 \pm 0.7)^\circ \,, \tag{77.6}$$

where only the solution consistent with the Standard Model is reported (methods to resolve the trigonometric ambiguity in the result are discussed below). It is also possible to use data-driven methods, typically based on flavour symmetries plus some additional assumptions, to constrain the effects of penguin pollution [19–21]. In this case it is necessary to consider each charmonium-kaon final state separately, since the penguin pollution to each may differ. The most common approach [19], which relies on experimental information on $B^0 \to J/\psi\pi^0$ decays, currently gives an additional uncertainty on $\sin(2\beta)$ from $B^0 \to J/\psi K^0_{\rm S}$ of around 0.01.

It is possible to avoid the issue of penguin pollution in the measurement of β by using B^0 meson decays to a charm- and light-meson final state, such as $D_{CP}\pi^0$ (where D_{CP} represents a D^0 meson decaying into a CP eigenstate), instead of the charmonium-kaon final states. These decays do have a CKM-suppressed contribution ($V_{ub}V_{cd}^*$ instead of $V_{cb}V_{ud}^*$), which can in principle bias the determination of $\sin(2\beta)$ from S_f, but this can be calculated and is known to be negligible at current precision. The requirement that the neutral D meson decays to a final state that is common to both D^0 and $\overline{D}^0$, such as the CP-even eigenstate K^+K^-, reduces the sample size that is available for analysis. Consequently, the world average [4], $\sin(2\beta) = 0.71 \pm 0.09$, with these channels is not as precise as that from the charmonium-kaon states.

Converting experimental results on $\sin(2\beta)$ into constraints on β leads to a trigonometric ambiguity in the range $[0°, 180°]$. This can be resolved with experimental measurements of $\cos(2\beta)$, which can be obtained from decay-time-dependent analyses of B^0 meson decays to multibody (non-CP-eigenstate) final states. Among the charmonium-kaon decays, study of $B^0 \to J/\psi K^*(892)^0$ with $K^*(892)^0 \to K^0_{\rm S}\pi^0$ is the most promising approach, but due to the limited sample size that has been analysed to date the precision is not sufficient to resolve the ambiguity conclusively. The charm- and light-meson channels such as $B^0 \to D\pi^0$ with $D \to K^0_{\rm S}\pi^+\pi^-$ have been shown to provide good statistical power for this purpose, with a joint analysis of BaBar and Belle data giving $\cos(2\beta) = 0.91 \pm 0.25$ [22,23], sufficient to rule out the alternative solution for β.

77.3 α

In the limit that only tree amplitudes contribute to B^0 meson decays to light mesons, such as $B^0 \to \pi^+\pi^-$, then the observables of the decay-time-dependent CP asymmetry of Eq. (77.3) would allow a straight-forward determination of 2α: $S_f = +\eta_{CP}\sin(2\alpha)$

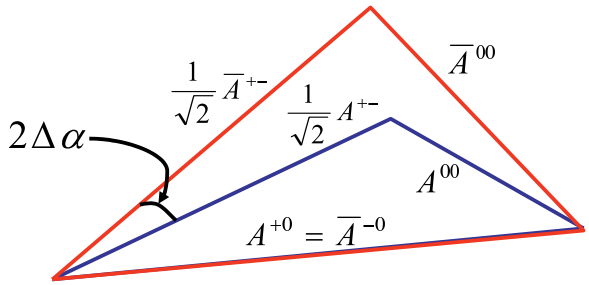

Figure 77.1: Isospin triangles for $B \to \pi\pi$ decays, reproduced from Ref. [24]. Here, the relative phase between A^{+0} and $\overline{A}^{-0}$ has been rotated away to simplify the picture. The total relative phase probed by $S_{\pi^+\pi^-}$ is $\arg\left(\frac{q}{p}\frac{\overline{A}^{+-}}{A^{+-}}\right) = 2\alpha - 2\Delta\alpha$, including contributions from B^0–$\overline{B}^0$ mixing, the tree-level amplitudes and the correction $\Delta\alpha$, and exploiting the unitarity requirement $\alpha + \beta + \gamma = 180°$.

and $C_f = 0$. In general, however, the determination of α is complicated by the presence of contributions from $b \to d(u\bar{u})$ neutral-current penguin transitions, which have a similar level of CKM-suppression as the $b \to u(\bar{u}d)$ charged-current tree amplitudes but have a different weak phase. Consequently, one obtains instead for $B^0 \to \pi^+\pi^-$

$$S_{\pi^+\pi^-} = \sqrt{1 - C^2_{\pi^+\pi^-}}\,\sin(2\alpha - 2\Delta\alpha), \qquad (77.7)$$

where $\Delta\alpha$ is the *a priori* unknown penguin contribution.

This contribution from the penguin amplitude can be accounted for in an analysis relating the amplitudes for isospin partner decays, *e.g.* A^{+-} for $B^0 \to \pi^+\pi^-$, A^{+0} for $B^+ \to \pi^+\pi^0$, A^{00} for $B^0 \to \pi^0\pi^0$ decays and $\left(\overline{A}^{+-}, \overline{A}^{-0}, \overline{A}^{00}\right)$ for their charge conjugates. The isospin analysis relies on the fact that there is no penguin contribution to A^{+0} and $\overline{A}^{-0}$, because $\pi^\pm\pi^0$ is a pure isospin-2 state, and the ($\Delta I = \frac{1}{2}$) QCD-penguin amplitudes only contribute to the isospin-0 final state. One therefore obtains the following isospin triangle relations [25]

$$A^{+0} = \frac{1}{\sqrt{2}}A^{+-} + A^{00} \quad \text{and} \quad \overline{A}^{-0} = \frac{1}{\sqrt{2}}\overline{A}^{+-} + \overline{A}^{00}\,, \quad (77.8)$$

from which it is possible to determine $\Delta\alpha$, as shown in Fig. 77.1.

Since the determination of $\Delta\alpha$ and thus also α requires construction of amplitude-level relations, it is not appropriate to simply average results of α from different experiments. Instead, measurements of each of the observable quantities needed to determine α are input into a combination. For the $B \to \pi\pi$ system, the inputs are the branching fractions of $B^0 \to \pi^+\pi^-$, $B^+ \to \pi^+\pi^0$ and $B^0 \to \pi^0\pi^0$ decays, the lifetimes of the B^+ and B^0 mesons (which relate the branching fractions to amplitude-level quantities), and the $S_{\pi^+\pi^-}$, $C_{\pi^+\pi^-}$ and $C_{\pi^0\pi^0}$ observables. Potential sources of correlation must be taken into account, but these are predominantly systematic in origin and thus have a small effect on the combination, since the measurements are statistically limited. An exception is that the LHCb measurements of $(S_{\pi^+\pi^-}, C_{\pi^+\pi^-})$ [26,27] have a significant statistical correlation due to the fact that the time variable of Eq. (77.3) is the difference between production and decay, and hence is in the range $[0, \infty]$. This correlation is largely absent for measurements from BaBar [28] and Belle [29], where the difference between the signal and tagging B meson decay times is measured, and hence $t \in [-\infty, \infty]$. The combination itself can be performed with different statistical approaches; the procedure described in detail in Ref. [30], based on a frequentist treatment, is used here. The knowledge of $C_{\pi^0\pi^0}$ [28,31] is currently the limiting factor in the precision on α from the $B \to \pi\pi$ system, and is likely to remain so for some time due to the difficulty to reconstruct this final state.

In general, the isospin triangle construction gives a four-fold ambiguity on $2\Delta\alpha$ (each triangle can face either up or down), leading to an eight-fold ambiguity on α in the range $[0°, 180°]$. This is reduced if either or both of the triangles are flat, or if the two triangles have sides of identical length. The ambiguities can also be reduced if measurement of the $S_{\pi^0\pi^0}$ (or equivalent) observable is available, since this can be combined with the corresponding $\Delta\alpha$ parameter from the right-hand corner of the triangle in Fig. 77.1 to provide an additional constraint. None of these possibilities are realised in the $B \to \pi\pi$ system; in particular a decay-time-dependent analysis of $B^0 \to \pi^0\pi^0$ is extremely challenging experimentally due to the absence of any charged particle originating from the B decay position. Nonetheless, solutions consistent with $\alpha = 0$ can be rejected on physical grounds [24].

The isospin analysis can also be performed with the $B \to \rho\rho$ system, which contains two vector particles in the final state and so does not have a fixed CP eigenvalue. In principle the analysis can be performed separately for each $\rho\rho$ polarization state, but in practise it is found that the longitudinal polarization fraction, f_L, is close to unity, and hence the final state is approximately CP-even. Compared to $B^0 \to \pi\pi$, the $\rho\rho$ modes benefit experimentally from a higher branching fraction and smaller penguin contributions, so that the isospin triangles are flatter, reducing the ambiguities. (The value of $\Delta\alpha$ in the $B \to \rho\rho$ system, obtained from the isospin analysis, has a single solution in $[0, \pi]$ at $(3 \pm 5)°$, while for $B \to \pi\pi$ there are two solutions at 13° and 27° with $\Delta\alpha \in [7, 33]°$ at 68.3% confidence level (CL). The isospin analysis with either final state has an ambiguity under $\Delta\alpha \Leftrightarrow -\Delta\alpha$.) For the BaBar [32] and Belle [33] experiments, the high branching fraction and smaller penguin contribution compensate for the increased difficulty to reconstruct the $\rho\rho$ final state relative to $\pi\pi$. Moreover, in contrast to $S_{\pi^0\pi^0}$, measurement of $S_{\rho^0\rho^0}$ is possible due to the four charged pion final state, following $\rho^0 \to \pi^+\pi^-$ decay, as has been demonstrated by BaBar [34].

In the $B \to \rho\pi$ system there are more amplitudes to consider, so that the isospin relation corresponds to a pentagon rather than a triangle and Eq. (77.8) is modified to become

$$\begin{aligned}\sqrt{2}(A^{+0} + A^{0+}) &= A^{+-} + A^{-+} + 2A^{00} \quad \text{and} \\ \sqrt{2}(\overline{A}^{-0} + \overline{A}^{0-}) &= \overline{A}^{+-} + \overline{A}^{-+} + 2\overline{A}^{00}\,.\end{aligned} \qquad (77.9)$$

As in Eq. (77.8), the left-hand sides of these expressions correspond to a pure isospin-2 final state, and therefore the ratio of the right-hand sides gives a pure phase term that, accounting for the B^0–$\overline{B}^0$ mixing phase that also contributes to the measured quantities, is 2α. The relative amplitudes for B^0 and $\overline{B}^0$ decays to $\rho^+\pi^-$, $\rho^-\pi^+$ and $\rho^0\pi^0$ can all be determined from a decay-time-dependent analysis of the $\pi^+\pi^-\pi^0$ Dalitz plot, so that study of this channel alone allows determination of α [35]. This analysis in principle leads to a single solution for α in $[0°, 180°]$, but the precision of current measurements [36–38] is limited.

The isospin analysis used to determine α is believed to be valid to high precision, and theoretical uncertainties in the procedure are usually neglected. Nonetheless, it should be noted that the analysis assumes the absence of electroweak penguin amplitudes, which can contribute to $\Delta I = \frac{3}{2}$ transitions with a different weak phase from that of the tree amplitudes [39,40]. Moreover, isospin-breaking effects such as $\left(\pi^0, \eta, \eta'\right)$ mixing would impact on the relations of Eq. (77.8). A further complication in the $B \to \rho\rho$ system is the effect of the non-zero ρ meson width [41]. Estimates of the size of these effects on the determined value of α are typically at the 1° level or less [30]. By contrast, methods to determine α using SU(3) or other flavour symmetries are generally considered to have larger theoretical uncertainties and are not included here.

The world average obtained for the angle α from isospin analysis of $B \to \pi\pi$, $\rho\pi$ and $\rho\rho$ decays is [4]

$$\alpha = (85.2\,^{+4.8}_{-4.3})°\,, \qquad (77.10)$$

where the quoted uncertainty is at the 68.3% CL and does not include effects due to isospin-breaking. This world average, together with results split by decay mode, is shown in Fig. 77.2. The combination has a total of 51 experimental inputs from which 24 parameters are determined, and an overall χ^2 of 16.6, which corresponds to a p-value of 94%. Thus, there is excellent overall consistency between the inputs, despite the tension apparent in

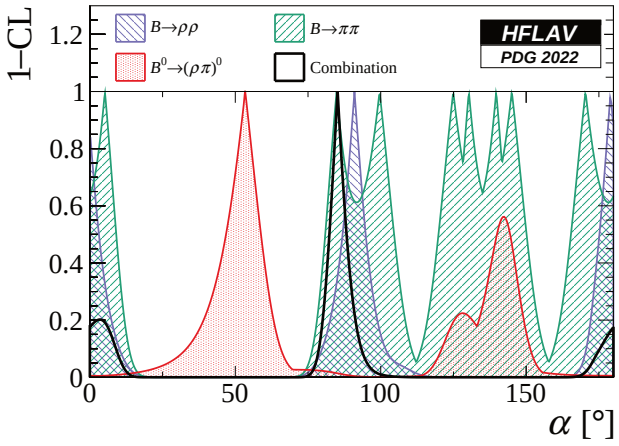

Figure 77.2: World average of α, as well as contributions from individual modes, in terms of 1−CL.

Fig. 77.2 between the results from $B^0 \to (\rho\pi)^0$ and the others. The combination gives a single best-fit for α in $[0°, 180°]$, but an ambiguous solution exists at $\alpha \Leftrightarrow \alpha{+}180°$. A secondary minimum close to zero is disfavoured [30].

77.4 γ

The angle γ is the weak phase between Cabibbo-favoured $b \to c$ and suppressed $b \to u$ quark transitions and can be determined by exploiting interference between them. Explicitly, the ratio of suppressed to favoured amplitudes is parameterized by

$$r_B e^{i(\delta_B \pm \gamma)} = \frac{A_{\rm sup}}{A_{\rm fav}} , \qquad (77.11)$$

where r_B is the ratio of amplitude magnitudes, δ_B the strong phase difference and the + or − sign depends on whether the transition involves a $\bar{b}$ or b quark, respectively. Measurement of γ in this way has negligible theoretical uncertainty in the Standard Model [42], and therefore this approach provides a benchmark against which determinations from other methods, typically involving loop diagrams, can be compared.

Interference between these amplitudes is realised in $B^+ \to DK^+$ decays, where D represents an admixture of D^0 and $\overline{D}^0$ mesons. The simplest case is that of D decays to *CP*-eigenstates (GLW method [43, 44]), either *CP*-even such as K^+K^- (*CP*+) or *CP*-odd such as $K^0_S\pi^0$ (*CP*−). The normalized decay rate and *CP* asymmetry are given by

$$R_{CP\pm} = \frac{\Gamma(B^- \to D_{CP\pm}K^-) + \Gamma(B^+ \to D_{CP\pm}K^+)}{\Gamma(B^- \to D^0K^-) + \Gamma(B^+ \to \overline{D}^0K^+)}$$
$$= 1 + r_B^2 \pm 2r_B\cos(\delta_B)\cos(\gamma) , \qquad (77.12a)$$
$$A_{CP\pm} = \frac{\Gamma(B^- \to D_{CP\pm}K^-) - \Gamma(B^+ \to D_{CP\pm}K^+)}{\Gamma(B^- \to D_{CP\pm}K^-) + \Gamma(B^+ \to D_{CP\pm}K^+)}$$
$$= \frac{\pm 2r_B\sin(\delta_B)\sin(\gamma)}{1 + r_B^2 \pm 2r_B\cos(\delta_B)\cos(\gamma)} . \qquad (77.12b)$$

These relations assume the absence of direct *CP* violation in the charm system; experimentally allowed deviations from this assumption are too small to cause a significant bias on γ [7, 45]. It is convenient to determine the $R_{CP\pm}$ quantities through a double ratio, normalizing to $B^+ \to D\pi^+$ decays involving the same final states, since this cancels potential sources of systematic uncertainty due to the branching fractions of the D decays that are used; small possible effects of *CP* violation in $B^+ \to D\pi^+$ decays are a source of systematic uncertainty in this procedure. The GLW method can be extended to include final states that are almost *CP*-eigenstates [46], as is the case in $D \to \pi^+\pi^-\pi^0$ and $D \to K^+K^-\pi^0$ decays, via inclusion of a factor encoding the fraction of *CP*-even (or *CP*-odd) content, $F_\pm$, which dilutes the sensitivity to γ by reducing the size of the interference terms (the terms linear with r_B) in Eq. (77.12).

For other D decays, the ratio of amplitudes for the D^0 and $\overline{D}^0$ decays to the final state of interest has to be accounted for in the formalism. The ADS method [47, 48] uses D decays to final states such as $K^\mp\pi^\pm$, which involve interference between Cabibbo-favoured (CF) and doubly-Cabibbo-suppressed (DCS) transitions. The observables in this case are

$$A_{\rm ADS} = \frac{\Gamma(B^- \to [K^+\pi^-]_D K^-) - \Gamma(B^+ \to [K^-\pi^+]_D K^+)}{\Gamma(B^- \to [K^+\pi^-]_D K^-) + \Gamma(B^+ \to [K^-\pi^+]_D K^+)}$$
$$= \frac{2r_B r_D\sin(\delta_B + \delta_D)\sin(\gamma)}{r_B^2 + r_D^2 + 2r_B r_D\cos(\delta_B + \delta_D)\cos(\gamma)} , \qquad (77.13a)$$
$$R_{\rm ADS} = \frac{\Gamma(B^- \to [K^+\pi^-]_D K^-) + \Gamma(B^+ \to [K^-\pi^+]_D K^+)}{\Gamma(B^- \to [K^-\pi^+]_D K^-) + \Gamma(B^+ \to [K^+\pi^-]_D K^+)}$$
$$= r_B^2 + r_D^2 + 2r_B r_D\cos(\delta_B + \delta_D)\cos(\gamma) , \qquad (77.13b)$$

where r_D and δ_D are the amplitude magnitude ratio and strong phase difference between the CF and DCS D decay. An alternative pair of observables, (R_-, R_+), is also sometimes used, where R_- (R_+) is the ratio of decay rates between the suppressed and favoured transitions for B^- (B^+) decays. The R_- and R_+ observables are statistically independent, while $A_{\rm ADS}$ and $R_{\rm ADS}$ are not (in particular, the uncertainty on $A_{\rm ADS}$ depends on the central value of $R_{\rm ADS}$). However, the pair (R_-, R_+) has more correlated sources of systematic uncertainty compared to $(A_{\rm ADS}, R_{\rm ADS})$. The observables of Eq. (77.13) are therefore usually preferred once a significant signal is established. The ADS method can also be extended to include decays to multibody final states, such as $D \to K^\pm\pi^\mp\pi^0$ and $D \to K^\pm\pi^\mp\pi^+\pi^-$, by addition of a coherence factor [49] which appears in the interference terms of Eq. (77.13) and accounts for dilution of the sensitivity due to variation of the decay amplitude across the phase space of the final state. A similar method can be used for singly Cabibbo-suppressed D decays to non-*CP* eigenstates such as K^*K [50].

For D decays to multibody self-conjugate final states (BPGGSZ method [51,52]), such as $D \to K^0_S\pi^+\pi^-$, one can write the partial decay rate as a function of the position in the phase space in terms of the "Cartesian parameters" $x_\pm + iy_\pm = r_B e^{i(\delta_B \pm \gamma)}$:

$$d\Gamma(B^\pm \to [K^0_S\pi^+\pi^-]_D K^\pm) = A^2_{(\mp,\pm)} + r_B^2 A^2_{(\pm,\mp)}$$
$$+ 2A_{(\pm,\mp)}A_{(\mp,\pm)}[x_\pm c_{D(\pm,\mp)} + y_\pm s_{D(\pm,\mp)}], \qquad (77.14)$$

where the notation $(+,-)$ is shorthand for the dependence on the Dalitz-plot position — the squared invariant masses of $K^0_S\pi^+$ and $K^0_S\pi^-$ combinations, respectively. The quantities $A_{(+,-)}$ and $A_{(-,+)}$ represent the magnitudes of the D^0 and $\overline{D}^0$ decay amplitudes at the position $(+,-)$ and are interchangable with their *CP* conjugate amplitudes because *CP* conservation is assumed in the D decay (*i.e.* $A_{(-,+)} = \overline{A}_{(+,-)}$). The quantities $c_{D(\pm,\mp)}$ and $s_{D(\pm,\mp)}$ are the cosine and sine of the strong phase difference, $\delta_{D(+,-)} = \arg(\overline{A}_{(+,-)}) - \arg(A_{(+,-)})$, between the $\overline{D}^0$ and D^0 amplitudes. These quantities can be determined from an amplitude model, although this leads to a hard-to-quantify systematic uncertainty associated to the composition of the model. An alternative, "model-independent", approach involves dividing the phase space into appropriate bins. In this case, the analysis benefits from external input on the values of c_D and s_D integrated over each bin. Measurements of these external parameters have been performed for the $D \to K^0_S\pi^+\pi^-$ decay by the CLEO-c and BESIII collaborations [53–56]. The use of common input values for these parameters in model-independent determinations of γ with the BPGGSZ method by different experiments is a source of correlation between experiments that is currently negligible but will become more significant as the available B meson data samples increase in size.

The discussion above refers to $B^+ \to DK^+$ decays, but analogous measurements can be made also for additional channels such as $B^+ \to D^*K^+$ (with $D^* \to D\pi^0$, $D\gamma$) and $B^+ \to DK^{*+}$ (with $K^{*+} \to K^0_S\pi^+$, $K^+\pi^0$). In the limit that these can be treated purely as two-body decays, the expressions for $B^+ \to DK^+$ are modified only by ensuring the r_B and δ_B parameters are specific to each B decay. Moreover, for $B^+ \to D^*K^+$ decays an effective

shift of the strong phase by π between $D^* \to D\pi^0$ and $D\gamma$ decays [57] has to be taken into account. In case the finite width of the decaying resonance is non-negligible, as is the case for the $K^*(892)$ state, additional amplitudes can contribute leading to a dilution of the sensitivity, which can be accounted for in the formalism through the introduction of a relevant coherence factor. For the $B^0 \to DK^{*0}$ decay, full amplitude analysis of the $B^0 \to DK^+\pi^-$ Dalitz plot provides additional sensitivity compared to the quasi-two-body approach [58, 59].

It is also possible to measure γ using decay-time-dependent analysis of the B_s^0 meson [60]. The weak phase arising in the interference between direct decay of $B_s^0 \to D_s^\mp K^\pm$ and decay via mixing is $(\gamma - 2\beta_s)$, where β_s is the angle associated with $B_s^0 \to J/\psi\phi$ decays in a similar way to the relation between β and $B^0 \to J/\psi K_S^0$ decays described in Sec. 77.2. Sufficient information can be obtained from the tagged, decay-time-dependent rates of $B_s^0 \to D_s^\mp K^\pm$ decays that this weak phase can be determined, up to an ambiguity, together with the strong phase difference between, and the ratio of the magnitudes of, the suppressed and favoured amplitudes. Since β_s is known to good precision [8], measurements of the decay-time-dependent *CP*-asymmetry observables in $B_s^0 \to D_s^\mp K^\pm$ decays can be used to infer constraints on γ. Alternatively, if effects of penguin pollution in $B_s^0 \to J/\psi\phi$ decays [17, 18] are a concern, as they will become in the future, results from the $B_s^0 \to D_s^\mp K^\pm$ mode can be combined with an independent precise measurement of γ to provide a penguin-free determination of β_s.

The average for γ requires a non-trivial combination due the complicated relations between the observables and the physics parameters of interest, such as in Eqs. (77.12), (77.13) and (77.14). Moreover, hadronic parameters such as r_B and δ_B defined in Eq. (77.11) are common to all different D decay modes (but differ for each B decay mode). Thus, it is not correct to simply average results for γ obtained by different experiments or in different channels. Instead, measurements of rate asymmetries, rate ratios and the Cartesian parameters are taken as inputs to the combination, from which results are obtained not only for γ but also for the hadronic parameters. Independent measurements of auxiliary parameters such as r_D and δ_D are also treated as inputs to the combination. In some cases the B decay data can help to reduce uncertainties on these auxiliary parameters and therefore a simultaneous fit of charm and beauty data can provide stronger constraints [61]; this approach however is not currently used for the world average.

The precision to which γ can be measured with a particular B decay is approximately inversely proportional to the value of r_B. Thus, results from channels with smaller yields but larger values of r_B, such as $B^0 \to DK^{*0}$ and $B_s^0 \to D_s^\mp K^\pm$ ($r_B \approx 0.3$–0.4), can have a significant impact on the world average and are included in the combination. By contrast the $B^+ \to D\pi^+$ mode, for which large samples are available but $r_B \approx 0.005$, has little impact and is also more sensitive to potential systematic biases; hence it is not included. The sensitivity of the world average at present is dominated by results from $B^+ \to DK^+$, where $r_B \approx 0.1$, in particular results with the GLW [62], ADS [62] and BPGGSZ [63] methods.

The world average obtained for the angle γ, obtained by combining results from $B^+ \to DK^+$, D^*K^+, DK^{*+}, $DK^+\pi^+\pi^-$, $B^0 \to DK^+\pi^-$, $B_s^0 \to D_s^\mp K^\pm$ and $B_s^0 \to D_s^\mp K^\pm\pi^+\pi^-$ decays, is [4]

$$\gamma = \left(65.9\,^{+3.3}_{-3.5}\right)^\circ \ , \qquad (77.15)$$

where the quoted uncertainty is at the 68.3% CL.

Effects related to charm and kaon mixing and *CP* violation are generally negligible at the current level of precision, in particular for modes with $r_B \gtrsim 0.1$. An exception is that a dependence of the selection efficiency on the charm decay time can induce a dependence of the observables on charm mixing parameters [64]. Such effects can be important at hadron collider experiments such as LHCb, but can be and are corrected for. Interactions of neutral kaons with detector material can also cause a bias in determination of γ from modes with low values of r_B [65], such as the BPGGSZ method applied to $B^+ \to D\pi^+$, but are negligible in modes with larger r_B values. A further subtlety is that the identification of the weak phase between suppressed and favoured amplitudes in $B \to DK$ decays with γ, as defined in Eq. (77.2), assumes that the 2×2 submatrix of the CKM matrix is real, *i.e.* that $\arg\left[V_{ud}V_{us}^*/\left(V_{cd}V_{cs}^*\right)\right] = 0$. This is true to an excellent approximation in the Standard Model, and is known experimentally from independent studies of the charm system [45] to contribute negligible bias to current measurements. Nonetheless, in future it will be possible to test directly this assumption by comparing the value of γ obtained from the $B \to DK$ and $B \to D\pi$ systems.

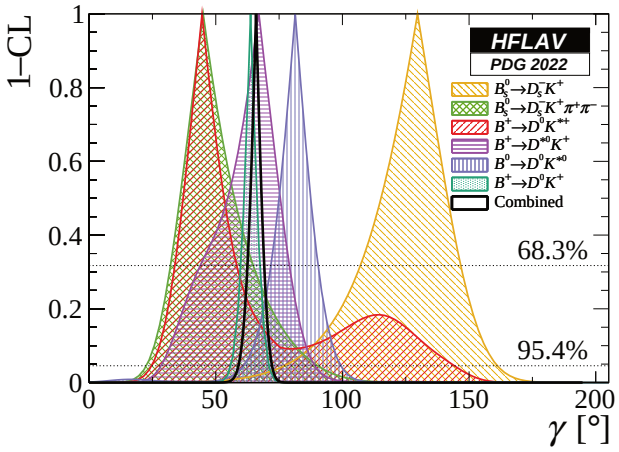

Figure 77.3: World average of $\gamma \equiv \phi_3$, as well as contributions from individual modes, in terms of 1−CL.

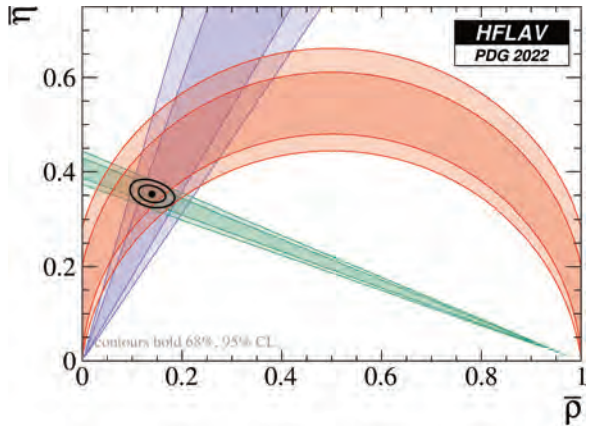

Figure 77.4: Constraints from the measurements of the angles of the CKM unitarity triangle in the $(\overline{\rho}, \overline{\eta})$ plane.

Effects from correlated uncertainties between amplitude models and strong phase differences in charm decays are negligible and are not explicitly accounted for in the combination, nor are effects related to charm and kaon mixing and *CP* violation. This world average, together with results split by decay mode, is shown in Fig. 77.3. The combination has a total of 154 experimental inputs from which 35 parameters are determined, an an overall χ^2 of 123.9, which corresponds to a p-value of 36% indicating good agreement between the inputs. The combination gives a single solution for γ in $[0°, 180°]$, but an ambiguous solution exists at $\gamma \Leftrightarrow \gamma + 180°$.

77.5 Summary

Experimental progress has resulted in all three angles of the CKM unitarity triangle being measured with good accuracy, with β known to subdegree precision and both α and γ known to better than 5°. The constraints from these three measurements in the $(\overline{\rho}, \overline{\eta})$ plane are shown in Fig. 77.4; further discussion and comparison with constraints from independent measurements can be found in Ref. [6]. The determinations of all three angles remain statistically limited, but it will be a challenge for experiments to

ensure that this remains the case as the precision improves. Consequently, the correct treatment of sources of correlation between the measurements that go into the world average combinations is becoming increasingly important.

78. Spectroscopy of Mesons Containing Two Heavy Quarks

Revised August 2021 by S. Eidelman (Budker Inst., Novosibirsk; Novosibirsk U.), J. J. Hernández-Rey (IFIC, Valencia), C. Lourenço (CERN), R.E. Mitchell (Indiana U.), S. Navas (Granada U.) and C. Patrignani (Bologna U.).

A golden age for heavy quarkonium physics dawned at the turn of this century, initiated by the confluence of exciting advances in quantum chromodynamics (QCD) and an explosion of related experimental activity. The subsequent broad spectrum of breakthroughs, surprises, and continuing puzzles had not been anticipated. Indeed, CLEO-c, BESIII, and the B-factories, later joined by ATLAS, CMS and LHCb, have made a series of groundbreaking observations. For an extensive presentation of the status of heavy quarkonium physics, the reader is referred to several reviews [1–7]. This note focuses on experimental developments in heavy quarkonium spectroscopy with very few theoretical comments. Possible theoretical interpretations of the states not predicted by the quark model are presented in the review "Heavy non-$q\bar{q}$ mesons." Note that in this review we follow the new naming scheme for hadrons (see the review "Naming scheme for hadrons" in the current edition).

This review covers states discovered since 2003, the year that marked the unexpected discovery of the $X(3872)$ [8]. The $X(3872)$, now called $\chi_{c1}(3872)$, was the first of the mesons containing two heavy quarks that could not be easily accommodated by the $q\bar{q}$ quark model. Its discovery was a watershed event in meson spectroscopy. In earlier versions of this write-up the particles were sorted according to an assumed *conventional* or *unconventional* nature with respect to the quark model. However, since this classification is not always unambiguous, we here follow Ref. [9] and sort the states into three groups, namely states below (*cf.* Table 78.1), above (*cf.* Table 78.2), and near (*cf.* Table 78.3) the lowest open-flavor thresholds.

78.1 States Below Open-Flavor Threshold

Table 78.1 lists properties of recently observed heavy quarkonium states located below the lowest open-flavor thresholds. Those are expected to be (at least prominently) conventional quarkonia. The majority of charmonium ($c\bar{c}$) and bottomonium ($b\bar{b}$) states were established prior to 2003.

78.1.1 *Charmonium*

The $h_c(1P)$ is the 1^1P_1 charmonium state, the singlet partner of the long-known χ_{cJ} triplet 1^3P_J. After being firmly established in 2005 through the process $\psi(2S) \to \pi^0 h_c(1P)$ [10], it has since been studied extensively by BESIII using large samples of $\psi(2S)$ decays. Exclusive hadronic decays of the $h_c(1P)$, strongly suppressed relative to the dominant radiative transition $h_c(1P) \to \gamma\eta_c(1S)$, were first observed in 2019 [11] and 2020 [12].

Belle reported an observation of the $\psi_2(1D)$ decaying to $\gamma\chi_{c1}$ with J^{PC} presumed to be 2^{--} [13]. This state is listed in Table 78.1 as $\psi_2(3823)$. Its existence was confirmed with high significance by BESIII [14]. While the negative C-parity is indeed established by its observed decay channel, the assignment of $J = 2$ was done by matching to the closest quark model state (1^3D_2) and requires experimental confirmation.

The 1^1D_2 state, or the $\eta_{c2}(1D)$, with a mass expected near 3820 MeV, has not yet been observed. Recently Belle performed a search in $B \to \eta_{c2}(1D)K(\pi)$ decays in the mass range 3795–3845 MeV and found no signal [15]. Thus, the $\eta_{c2}(1D)$ remains the only unobserved conventional charmonium state that does not have open-charm decays.

78.1.2 *Bottomonium*

The ground state of bottomonium, $\eta_b(1S)$, is well established. After the initial reports from BaBar in radiative decays of the $\Upsilon(3S)$ (observation) [16] and $\Upsilon(2S)$ (evidence) [17], Belle confirmed the existence of the $\eta_b(1S)$ with more than 5σ significance in radiative decays of the newly discovered $h_b(1P)$ [18, 19] and $h_b(2P)$ [18] (see next paragraph), as well as in $\Upsilon(2S)$ radiative decays [20]. Belle has also reported strong evidence for the $\eta_b(2S)$ [18], but it still needs confirmation at the 5σ level. Note that there are hints of tension in the $\eta_b(1S)$ mass as measured in radiative M1 and E1 transitions. In the M1 transition $\Upsilon(2S) \to \gamma\eta_b(1S)$ Belle measures a mass of $9394.8^{+2.7+4.5}_{-3.1-2.7}$ MeV/c^2 [20], while in the E1 transitions $h_b(1P, 2P) \to \gamma\eta_b(1S)$ Belle measures $9402.4 \pm 1.5 \pm 1.8$ MeV/c^2 [18]. This tension may point to an incomplete understanding of the $\eta_b(1S)$ lineshape in different production mechanisms.

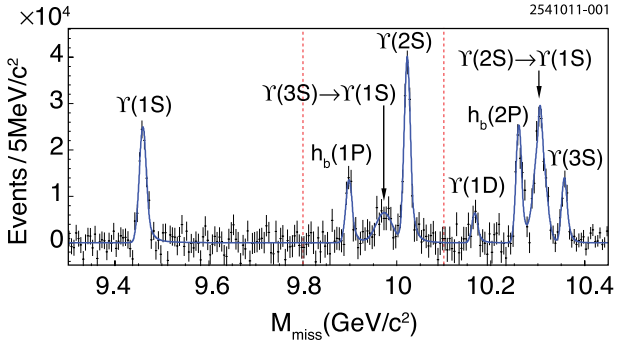

Figure 78.1: From Belle [21], the mass recoiling against $\pi^+\pi^-$ pairs, $M_{\rm miss}$, in e^+e^- collision data taken near the peak of the $\Upsilon(10860)$ (*points with error bars*). The smooth combinatorial and $K^0_S \to \pi^+\pi^-$ background contributions have been subtracted. The fit to the various labeled signal contributions is overlaid (*curve*).

The $h_b(1P)$, the bottomonium counterpart of the $h_c(1P)$, and the next excited state, the $h_b(2P)$, were simultaneously discovered by Belle using dipion transitions from the $\Upsilon(10860)$ [21] (Fig. 78.1). The same analysis also showed the $\Upsilon_J(1D)$, the lowest-lying D-wave triplet of the $b\bar{b}$ system, but did not resolve the $J = 1, 2, 3$ components. The search for the $h_b(1P)$ was directly inspired by a CLEO result [22], which found a surprisingly copious production of $e^+e^- \to \pi^+\pi^- h_c(1P)$ as well as an indication that $\psi(4230) \to \pi^+\pi^- h_c(1P)$ occurs at a comparable rate with the signature mode $\psi(4230) \to \pi^+\pi^- J/\psi(1S)$. The presence of $\Upsilon(nS)$ peaks in Fig. 78.1 at rates two orders of magnitude larger than expected, along with separate studies with exclusive decays $\Upsilon(nS) \to \mu^+\mu^-$, allow precise calibration of the $\pi^+\pi^-$ recoil mass spectrum and very accurate measurements of the $h_b(1P)$ and $h_b(2P)$ masses. Both corresponding hyperfine splittings are consistent with zero within an uncertainty of about 1.5 MeV (lowered to 1.1 MeV for the $h_b(1P)$ in Ref. [23]). Belle later observed the transition $\Upsilon(4S) \to h_b(1P)\eta$ [19] and the corresponding 1P hyperfine splitting was also found to be compatible with zero at a similar precision level.

Just before Christmas 2011, ATLAS offered the world a beautiful gift, in the form of the discovery of the $\chi_b(3P)$ quarkonium state [24], observed by combining dimuons from $\Upsilon(1S)$ or $\Upsilon(2S)$ decays with photons emitted in the radiative $\chi_b(3P)$ decays (Fig. 78.2, bottom left panel). The new resonance, with a mass of $10\,530 \pm 5(\text{stat}) \pm 9(\text{syst})$ MeV, was soon confirmed by D0 [25]. Also LHCb observed the $\chi_b(3P)$ peak, using the full Run 1 event sample, corresponding to an integrated luminosity of 3 fb^{-1} [26] (Fig. 78.2, middle left panel). Finally, CMS used 80 fb^{-1} of 13 TeV pp collisions, collected in 2016 and 2017, to show two well-resolved $\chi_{b1}(3P)$ and $\chi_{b2}(3P)$ peaks [27], separated by a mass difference of $10.60 \pm 0.64(\text{stat}) \pm 0.17(\text{syst})$ MeV (Fig. 78.2, top left panel). The remarkable precision of the individual mass measurements, with relative uncertainties as small as 50 ppm, shows that the LHC experiments can provide important results in the field of hadron spectroscopy, especially in the case of heavy particles, which require very high collision energies and large event samples.

78.1.3 B_c *System*

The $B_c^\pm$ family is quite special because these (charged) quarkonium states consist of two heavy quarks of different flavor. Among other interesting properties, this means that they cannot annihilate into gluons, the excited states only decaying to the pseudoscalar ground state, $B_c^\pm$, via electromagnetic and pionic transitions.

Table 78.1: New states below the open-flavor thresholds in the $c\bar{c}$, $b\bar{c}$, and $b\bar{b}$ regions, ordered by mass. Masses m and widths Γ represent the PDG21 weighted averages with statistical and systematic uncertainties added in quadrature. In the Production column, the state is always denoted by X. Ellipses (...) indicate inclusively selected event topologies, *i.e.*, additional particles not directly detected by experiment. A question mark (?) indicates an unmeasured value. The Discovery Year column gives the date of the first measurement cited. The Summary Table column indicates whether or not the state appears in the summary tables, usually requiring at least two independent experiments with significance of $>5\sigma$. Refer to the particle listings for references and further information.

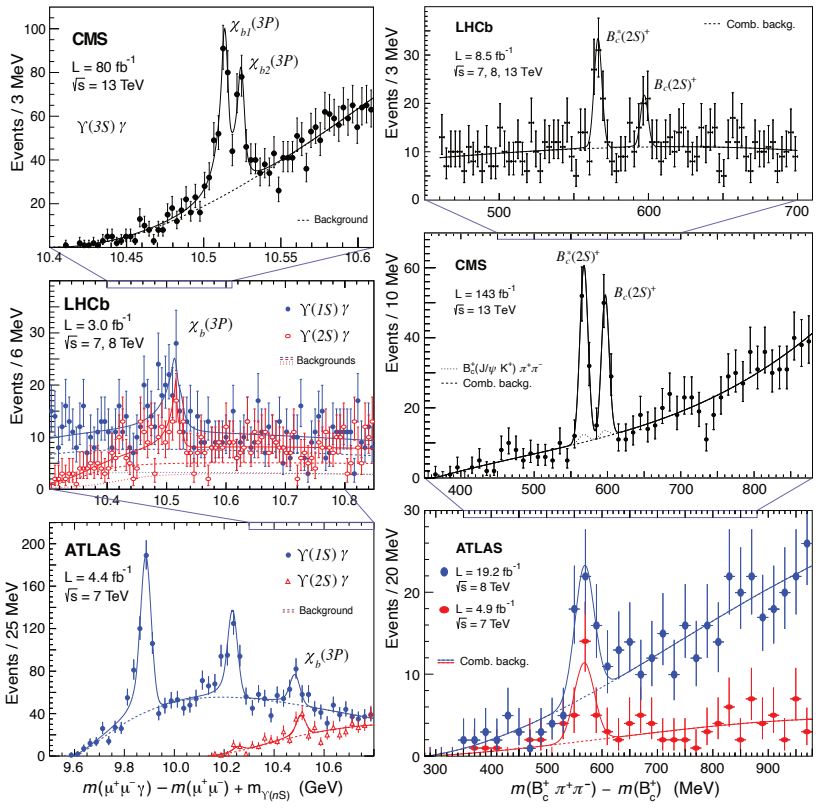

Figure 78.2: (Left Column) Invariant mass distributions measured by the ATLAS [24] (bottom), LHCb [26] (middle) and CMS [27] (top) experiments in their searches for the $\chi_b(3P)$ states through their radiative decays to one of the S-wave bottomonia. (Right Column) Invariant mass distributions measured by the ATLAS [28] (bottom), CMS [29] (middle) and LHCb [30] (top) experiments in their searches for $B_c^{\pm}$ excited states decaying to the $B_c^{\pm}$ ground state with the emission of two charged pions.

On the basis of an event sample collected in the Run 1 of the LHC, corresponding to an integrated luminosity of 24 fb^{-1}, adding the 7 and 8 TeV data, the ATLAS Collaboration observed a resonance in the $B_c^+\pi^+\pi^-$ invariant mass spectrum [28] (Fig. 78.2, bottom right panel). This peak, observed with a significance of 5.2 standard deviations and a mass of $6842 \pm 4(\text{stat}) \pm 5(\text{syst})$ MeV, was immediately recognized as the $B_c(2S)^\pm$ state, the first radial excitation in the $B_c^\pm$ family. Profiting from the much larger Run 2 event sample, collected in the 2015, 2016, 2017 and 2018 running periods and corresponding to 143 fb^{-1} of 13 TeV pp collisions, as well as from a measurement resolution of around 6 MeV, the CMS Collaboration could observe *two* well-resolved peaks, separated by $29.1 \pm 1.5(\text{stat}) \pm 0.7(\text{syst})$ MeV [29] (Fig. 78.2, middle right panel). The existence of two peaks, rather than a single one, is established with a significance of 6.5 standard deviations. The "right peak" has a mass of $6871.0 \pm 1.2(\text{stat}) \pm 0.8(\text{syst}) \pm 0.8(B_c^+)$ MeV, where the last term is the uncertainty in the B_c^+ mass, and is identified as the $B_c(2S)^\pm$ state, which decays directly to the $B_c^\pm$, emitting two (easy to detect) pions. The CMS observation, reported a couple of months after the end of the LHC Run 2, was soon followed by the corresponding LHCb result [30] (Fig. 78.2, top right panel), which confirmed the existence of the two states and reported a second measurement of the $B_c(2S)^\pm$ mass, $6872.1 \pm 1.3(\text{stat}) \pm 0.1(\text{syst}) \pm 0.8(B_c^+)$ MeV.

The "left peak" is interpreted as being the $B_c^*(2S)^\pm$ signal. It is observed at a mass lower than the real value because the experiments are unable to detect the low-energy photon emitted in the decay chain, $B_c^*(2S)^\pm \to B_c^{*\pm}\pi^+\pi^-$ followed by $B_c^{*\pm} \to B_c^\pm\gamma$ (Fig. 78.3). Its energy, expected to be in the range 40–80 MeV, leads to a very small probability that the photon converts into an e^+e^- pair and the two electrons are reconstructed. The relative ordering of the two peaks is based on a generally-agreed assumption: the $M(B_c^{*\pm}) - M(B_c^\pm)$ mass difference is larger than the $M(B_c^*(2S)^\pm) - M(B_c(2S)^\pm)$ difference. Naturally, these observations provide evidence for the existence of the $B_c^*(1S)^\pm$ state. They also provide measurements of two interesting mass differences, between the masses of the pseudoscalar mesons, $M(B_c(2S)^\pm) - M(B_c(1S)^\pm) = 596.1$ MeV, and of the vector mesons, $M(B_c^*(2S)^\pm) - M(B_c^*(1S)^\pm) = 567.0$ MeV (Fig. 78.3).

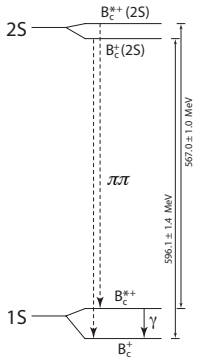

Figure 78.3: Diagram showing the decays mentioned in the text.

78.2 States Above Open-Flavor Threshold

Many states have been discovered both above and near the lowest open-flavor thresholds. They are displayed in Tables 78.2 and 78.3, respectively. With the exception of the $\psi_3(3842)$ and the tensor state located at 3930 MeV (now called $\chi_{c2}(3930)$), which have properties consistent with those expected for the $\psi_3(1^3D_3)$ and $\chi_{c2}(2^3P_2)$, respectively, none of these states can easily be assigned a place in the quark model spectrum of the charmonium or bottomonium families. At the same time, these states also have no universally accepted unconventional interpretation.

78.2.1 *Charmonium*

Using proton-proton collisions, LHCb observed a narrow state, the $\psi_3(3842)$ resonance, in the decay modes $\psi_3(3842) \to D^0\bar{D}^0$ and D^+D^- [31]. The mass and width of this state are measured to be $3842.71 \pm 0.16 \pm 0.12$ MeV and $2.79 \pm 0.51 \pm 0.35$ MeV, respectively. The observed mass and narrow width are consistent with the interpretation of the new state as the unobserved spin-3 $\psi_3(1^3D_3)$ charmonium. Accordingly, the state got the name $\psi_3(3842)$ in the listings, with the remark that the quantum numbers were fixed from the quark model and need to be confirmed.

The $\chi_{c2}(3930)$, which is a natural candidate for the $\chi_{c2}(2^3P_2)$ quark model state, was originally seen by Belle [32] and later confirmed by BaBar [33] in the $\gamma\gamma$ process $e^+e^- \to e^+e^-D\bar{D}$. This interpretation was strengthened by the more recent LHCb observation of the $\chi_{c2}(3930)$ alongside the $\psi_3(3842)$ in proton-proton collisions [31].

Unlike the $\chi_{c2}(2^3P_2)$, the identification of the $\chi_{c0}(2^3P_0)$ quark model state remains controversial. The original candidate was the $\chi_{c0}(3915)$, discovered by Belle in the $\gamma\gamma$ process $e^+e^- \to e^+e^-\omega J/\psi(1S)$ [34]. In a subsequent measurement by BaBar, its quantum numbers were determined to be $J^{PC} = 0^{++}$ [35]. However, its identification as the $\chi_{c0}(2^3P_0)$ quark model state was soon challenged [36, 37]. In addition, it was pointed out in Ref. [38] that if the assumption of helicity-2 dominance is abandoned and, instead, one allows for a sizeable helicity-0 component, a $J^{PC} = 2^{++}$ assignment is possible. This could imply that it is the same as the $\chi_{c2}(3930)$—but to explain the large helicity-0 component a sizable portion of non-$q\bar{q}$ is necessary [38]. A more recent LHCb amplitude analysis of the process $B^+ \to D^+D^-K^+$ finds distinct 0^{++} and 2^{++} components decaying to D^+D^- [39], which are currently identified in the listings as the $\chi_{c0}(3915)$ and $\chi_{c2}(3930)$, respectively.

An alternative candidate for the $\chi_{c0}(2^3P_0)$ (here referred to as the $\chi_{c0}(3860)$) was reported in Ref. [40] with properties more consistent with expectation: its mass is close to the potential model expectations, it decays to $D\bar{D}$, and the preferred quantum numbers are $J^{PC} = 0^{++}$ (this hypothesis is favored over the 2^{++} one with a 2.5σ significance).

In the excited vector charmonium spectrum, the $\psi(4040)$, $\psi(4160)$, and $\psi(4415)$ are prominent in the inclusive e^+e^- hadronic cross section and are naturally identified as the 3^3S_1, 2^3D_1, and 4^3S_1 $c\bar{c}$ quark model states, respectively. In addition to these long-established states, however, another set of mesons has been found as peaks in exclusive e^+e^- cross sections. Unlike conventional vector charmonia, they do not appear in the inclusive hadronic cross section and they apparently do not decay to $D\bar{D}$. The PDG summary table currently lists the $\psi(4230)$, $\psi(4360)$, and $\psi(4660)$ within this category. The first of these to be discovered was originally known as the $Y(4260)$ (now the $\psi(4230)$), seen by BaBar [41] and Belle [42, 43] in $e^+e^- \to \pi^+\pi^-J/\psi(1S)$ using initial state radiation. In a more recent high-statistics scan of $e^+e^- \to \pi^+\pi^-J/\psi(1S)$, BESIII demonstrated that the lineshape in this mass range is highly non-trivial [44]. The latter observation was interpreted by the authors as the presence of two states. However, this lineshape is also consistent with other possible interpretations, such as one assuming a molecular structure for the $\psi(4230)$ [45]. The data of Ref. [44] also called for a significant downward shift of the mass of what was originally called the $Y(4260)$, making it consistent with peaks in other exclusive cross sections, such as $h_c(1P)\pi\pi$ [46]. We thus merged the original $Y(4260)$ (or, more formally, the $\psi(4260)$) with the $\psi(4230)$ in the listings.

BESIII observed the $\chi_{c1}(3872)$, also known as $X(3872)$, in $e^+e^- \to \gamma\chi_{c1}(3872)$ in the $\psi(4230)$ mass range [47], which could allow for additional insight into the structure of both states (see the review on heavy non-$q\bar{q}$ mesons). BESIII also performed a recent study of the process $e^+e^- \to \pi^+\pi^-\psi(2S)$ and found evidence for a lower mass state, possibly the $\psi(4230)$, in addition to the more dominant $\psi(4360)$ [48].

Note that the data of Ref. [44] does not show any indication of the $Y(4008)$ reported by Belle; the data in this region can either be fit with a non-resonant background component or a much wider resonance at lower mass. Also the analysis of the $Y(4008)$ region in Ref. [49] indicates a wide resonance.

Table 78.2: As in Table 78.1, but for new states above the first open-flavor thresholds in the $c\bar{c}$ and $b\bar{b}$ regions, ordered by mass.

*Quantum numbers fixed from the quark model and need confirmation.

Another interesting question is whether a heavier $\pi^+\pi^-\psi(2S)$ state, the $\psi(4660)$, discovered by Belle [50, 51] and confirmed by BaBar [52], is identical to the $\Lambda_c^+\bar{\Lambda}_c^-$ resonance observed by Belle with a nearby mass and width [53]. Most probably it is, the $\Lambda_c^+\bar{\Lambda}_c^-$ being one more decay mode of the $\psi(4660)$ (see the review on heavy non-$q\bar{q}$ mesons for more detail). Note that this is the interpretation adopted in the particle listings. In addition, Belle reported the first observation of a vector charmonium-like state decaying to $D_s^+D_{s1}(2536)$ with a significance of 5.9σ [54]. Its measured mass and width are $4625.9^{+6.2}_{-6.0} \pm 0.4$ MeV and $49.8^{+13.9}_{-11.5} \pm 4.0$ MeV, respectively, consistent with those of the $\psi(4660)$. Therefore, $D_s^+D_{s1}(2536)$ appears as an additional decay mode of the $\psi(4660)$ in the listings.

A series of isovector states containing $c\bar{c}$ have been found in B decays to $K\pi(c\bar{c})$, where the isovector state decays to $\pi(c\bar{c})$ and $(c\bar{c})$ stands for $J/\psi(1S)$, $\psi(2S)$, or χ_{c1}. They are manifestly non-$q\bar{q}$ and their discovery implied an expansion of the meson naming scheme. The $Z_c(4430)$, decaying to $\pi\psi(2S)$, is the most well established. Based on a full amplitude analysis of $B^0 \to K^+\pi^-\psi(2S)$ decays, Belle determined the spin-parity of the $Z_c(4430)$ to be $J^P = 1^+$ [55]. From their study of $B^0 \to K^+\pi^-J/\psi(1S)$ decays, Belle also found evidence for the decay mode $Z_c(4430) \to \pi J/\psi(1S)$ [56], which has an order of magnitude lower branching fraction than the discovery mode $Z_c(4430) \to \pi\psi(2S)$. In the same analysis, Belle reported evidence for one more charged state, dubbed $Z_c(4200)$, decaying to $\pi J/\psi(1S)$. The existence of the $Z_c(4430)$ in $\pi\psi(2S)$, as well as its quantum number assignments, were confirmed by LHCb [57] with a much larger data sample, leading to improved mass and

width values, consistent with earlier measurements; the experiment even reports a resonant behavior of the $Z_c(4430)$ amplitude. The $Z_c(4430)$ was not confirmed (or excluded) by BaBar [58].

Belle also reported an observation of two charged states decaying to $\pi\chi_{c1}$ in an analysis of $B^0 \to K^+\pi^-\chi_{c1}$ decays [59]. These were originally called the $Z_1(4050)^\pm$ and the $Z_2(4250)^\pm$, but are referred to in Table 78.2 as $X(4050)^\pm$ and $X(4250)^\pm$. These states were not confirmed by BaBar [60]. Belle observes signals with 5.0σ significance for both the $Z_1(4050)^\pm$ and $Z_2(4250)^\pm$, whereas BABAR reports 1.1σ and 2.0σ effects, respectively, setting upper limits that are not inconsistent with Belle's measured rates. The situation remains unresolved.

The decay $B^+ \to K^+\phi J/\psi(1S)$ appears to be especially rich in resonant substructure. The $Y(4140)$ (now the $\chi_{c1}(4140)$), decaying to $\phi J/\psi(1S)$, was first observed in 2008 by CDF [61,62], and confirmed by D0 and CMS [63,64]. However, a second structure, the $Y(4274)$ (now the $\chi_{c1}(4274)$), could not be established unambiguously. Neither of the two states was seen in B decays at Belle [65], LHCb [66] and BaBar [67], or in $\gamma\gamma$ collisions at Belle [68]. The real breakthrough happened when LHCb performed a full amplitude analysis of $B^+ \to K^+\phi J/\psi(1S)$ with $J/\psi(1S) \to \mu^+\mu^-$, $\phi \to K^+K^-$ decays and showed that the data cannot be described in a model that contains only excited kaon states decaying into $K^+\phi$ [69,70]. They observe two 1^{++} states with masses close to those originally reported by CDF (the $\chi_{c1}(4140)$ and $\chi_{c1}(4274)$), but the width of the one at 4140 MeV is much larger. In addition, they find two significant 0^{++} structures at 4500 and 4700 MeV (the $\chi_{c0}(4500)$ and $\chi_{c0}(4700)$).

78.2.2 *Bottomonium*

Belle reported a new measurement of the $e^+e^- \to \Upsilon(nS)\pi^+\pi^-$ ($n = 1,2,3$) cross sections at energies from 10.52 to 11.02 GeV [71]. They observed, with a 5.2σ significance, a new structure in the energy dependence of the cross sections. If described by a Breit–Wigner function, its mass and width are $10752.7 \pm 5.9^{+0.7}_{-1.1}$ MeV and $35.5^{+17.6+3.9}_{-11.3-3.3}$ MeV, respectively. The new structure could have a resonant origin and correspond to the not yet observed $\Upsilon(3D)$ state, provided $S-D$ mixing is enhanced, or an exotic state, e.g., a compact tetraquark or hadrobottomonium. It could also be a non-resonant effect due to rescattering.

We no longer mention a hypothetical $Y_b(10888)$ state since a new analysis of the $\Upsilon(10860)$ energy range does not show evidence for an additional state with a mass different from that of the $\Upsilon(10860)$ [72]. After the mass of the $\eta_b(1S)$ was shifted upwards by about 10 MeV based on the Belle measurements [18,19], all of the bottomonium states mentioned above fit into their respective spectroscopies, roughly where expected. An independent experimental confirmation of the shifted masses came from the Belle observation of $\Upsilon(4S) \to \eta h_b(1P)$ decays [19]. This process turns out to be the strongest observed transition of the $\Upsilon(4S)$ to lower bottomonium states.

78.3 States Near Open-Flavor Threshold

A number of states, listed in Table 78.3, appear near open-flavor thresholds, which is likely an important factor in their theoretical interpretation [73].

78.3.1 *Charmonium*

The $\chi_{c1}(3872)$, also known as $X(3872)$, is widely studied and seen in many transitions — see Table 78.3. Yet its interpretation remains unsettled (see the heavy non-$q\bar{q}$ review). Its unique experimental features include: it has $J^{PC} = 1^{++}$ [74,75], yet it is too light to be the $\chi_{c1}(2^3P_1)$ quark model state; its mass is within 200 keV of the $D^0\bar{D}^{0*}$ threshold; it shows substantial isospin-breaking in its decays to $\rho J/\psi(1S)$ and $\pi^0\chi_{c1}$; and it is extremely narrow. Using a large sample of inclusively produced $\chi_{c1}(3872)$ decaying to $\pi^+\pi^- J/\psi(1S)$, LHCb recently determined the decay width of the $\chi_{c1}(3872)$ under two different assumptions [76]. Assuming a Flatté-inspired line shape and exploiting the strong coupling of the $\chi_{c1}(3872)$ to $D^0\bar{D}^{*0}$, LHCb performed the first exploration of the pole structure of the $\chi_{c1}(3872)$, finding a FWHM of $0.22^{+0.06+0.25}_{-0.08-0.17}$ MeV. On the other hand, assuming a Breit–Wigner line shape, its width was found to be $1.39 \pm 0.24 \pm 0.10$ MeV. While the former analysis has a more firm theoretical foundation, the LHCb detector resolution did not allow for a distinction between the different line shapes.

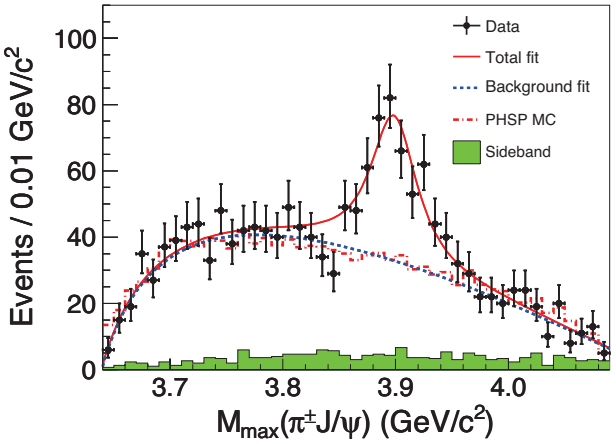

Figure 78.4: The $\pi^\pm J/\psi(1S)$ invariant mass distribution from BESIII [78] e^+e^- collision data taken at a center-of-mass energy near 4260 MeV.

In addition to the Z_c states found in B decays, discussed above, several isovector states with masses near $D\bar{D}^*$ and $D^*\bar{D}^*$ thresholds appear to be unique to e^+e^- annihilation. In 2013, a state named $Z_c(3900)$ was unearthed in the charmonium region at BESIII [78] and Belle [43] in the process $e^+e^- \to \pi^\mp Z_c(3900)^\pm$ with $Z_c(3900)^\pm \to \pi^\pm J/\psi(1S)$. The corresponding spectrum from BESIII is shown in Fig. 78.4. An analysis of CLEO data [79] confirmed this finding and also provided evidence for a neutral partner. A nearby signal was also seen in the $D\bar{D}^*$ channel [80] whose quantum numbers were fixed to 1^{+-}. BESIII reported its neutral partner in both $J/\psi(1S)\pi^0$ [81] and $D\bar{D}^*$ [82] decay modes. The masses extracted from these experiments in different decay modes have differences reaching up to 2σ. However, since the extraction of the mass and width parameters did not allow for an interference with the background and used Breit–Wigner line shapes, which is not justified near thresholds, there might be some additional systematic uncertainty in the mass values. Therefore, in the RPP listings as well as in Table 78.3 both structures appear under the name $Z_c(3900)$. BESIII also reported an observation of another charged state, the $X(4020)^\pm$ (originally called $Z_c(4020)^\pm$), in two decay modes: $h_c\pi^\pm$ [83] and $(D^*\bar{D}^*)^\pm$ [84]. The neutral partners have also been observed by BESIII in the $h_c\pi^0$ [85] and $(D^*\bar{D}^*)^0$ [86] final states. The Z_c states show some remarkable similarities to the Z_b states (discussed below), e.g. they decay dominantly to $D^{(*)}\bar{D}^*$ channels. However, current analyses suggest that the mass of the $Z_c(3900)$ might be somewhat above the $D\bar{D}^*$ threshold. If confirmed, this feature would challenge a possible $D\bar{D}^*$–molecular interpretation with S-wave interactions only — prominent D-waves can shift molecular poles above threshold (see the discussion in Sec. 78.3.2). Finally, 3.5σ evidence for one more charged charmonium-like state at 4055 MeV decaying into $\psi(2S)\pi^\pm$ was reported by Belle in their analysis of the process $e^+e^- \to \psi(2S)\pi^+\pi^-$ [51]. This state was confirmed by BESIII, although there appears to be complications in the Dalitz plot requiring further investigation [48].

78.3.2 *Bottomonium*

New results on the η_b, h_b, and Z_b mostly come from Belle [18,19, 21,23,72,87–93], all from analyses of 121.4 fb^{-1} of e^+e^- collision data collected near the peak of the $\Upsilon(10860)$ resonance, as well as from an additional 25 fb^{-1} of data collected during the scans of the c.m. energy range 10.63–11.05 GeV. The η_b, h_b, and Z_b appear in the decay chains $\Upsilon(10860) \to \pi^- Z_b^+$, $Z_b^+ \to \pi^+(b\bar{b})$, and, when the $b\bar{b}$ forms an $h_b(1P)$, frequently decaying as $h_b(1P) \to \gamma\eta_b$.

Belle soon noticed that, for events in the peaks of Fig. 78.1, there seemed to be two intermediate charged states, the $Z_b(10610)$ and the $Z_b(10650)$. For example, Fig. 78.5 shows a Dalitz plot for events restricted to the $\Upsilon(2S)$ region of $\pi^+\pi^-$ recoil mass,

Table 78.3: As in Table 78.1, but for new states near the first open-flavor thresholds in the $c\bar{c}$ and $b\bar{b}$ regions, ordered by mass. Updated from Ref. [77] with kind permission, copyright (2011), Springer, and from Ref. [9] with kind permission from the authors.

$Z_b(10650)$		10652.2 ± 1.5	11.5 ± 2.2	$1^+(1^{+-})$	$\Upsilon(10860) \to \pi^- X$	$\pi^+\Upsilon(1S, 2S, 3S)$ $\pi^+ h_b(1P, 2P)$ $(B^*\bar{B}^*)^+$	2011	YES

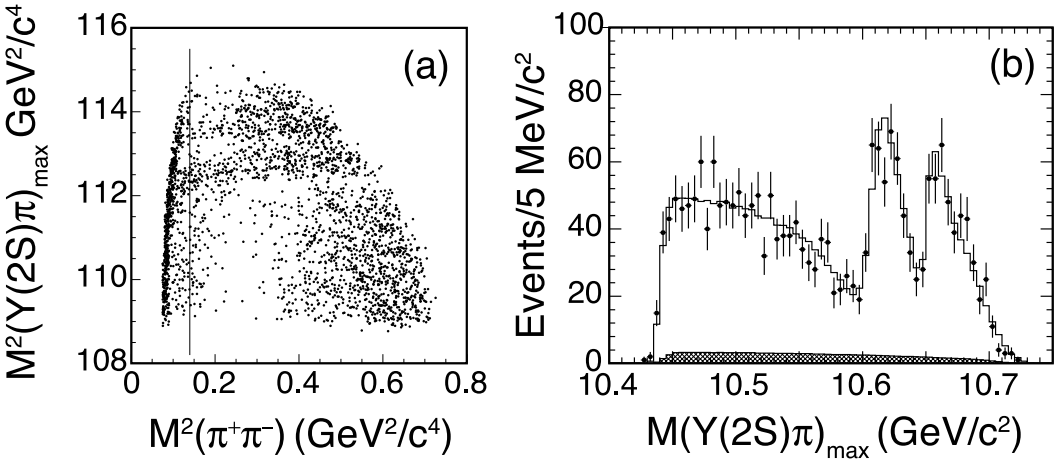

Figure 78.5: From Belle [87] e^+e^- collision data taken near the peak of the $\Upsilon(10860)$ for events with a $\pi^+\pi^-$-missing mass consistent with an $\Upsilon(2S) \to \mu^+\mu^-$, (a) the maximum of the two possible single $\pi^\pm$-missing-mass-squared combinations vs. the $\pi^+\pi^-$-mass-squared; and (b) projection of the maximum of the two possible single $\pi^\pm$-missing-mass combinations (*points with error bars*) overlaid with a fit (*curve*). Events to the left of the vertical line in (a) are excluded from the amplitude analysis. The hatched histogram in (b) corresponds to the combinatorial background. The two horizontal stripes in (a) and two peaks in (b) correspond to the two Z_b states.

with $\Upsilon(2S) \to \mu^+\mu^-$ [87]. The two bands observed in the maximum of the two $M[\pi^\pm\Upsilon(2S)]^2$ values also appear in the $\Upsilon(1S)$, $\Upsilon(3S)$, $h_b(1P)$, and $h_b(2P)$ samples. Belle fits all subsamples to resonant plus non-resonant amplitudes, allowing for interference (notably, between $\pi^- Z_b^+$ and $\pi^+ Z_b^-$), and finds consistent pairs of Z_b masses for all bottomonium transitions, and comparable strengths of the two states. A recent angular analysis assigned $J^P = 1^+$ for both Z_b states [88], which must also have negative G-parity. Transitions through Z_b to the $h_b(nP)$ saturate the observed $\pi^+\pi^- h_b(nP)$ cross sections. While the two masses of the Z_b states as extracted from Breit–Wigner fits for the various channels are just a few MeV above the $B^*\bar{B}$ and $B^*\bar{B}^*$ thresholds, more refined analyses using only S-waves find pole locations right below the corresponding thresholds either on the physical [94] or the unphysical [95] sheet. Once D-waves are included, the pole of the $Z_b(10650)$ moves above the $B^*\bar{B}^*$ threshold [96]. Regardless of their proximity to the corresponding thresholds, both states predominantly decay into these open-flavor channels [90, 97] with branching fractions that exceed 80% and 70%, respectively, at 90% CL. This feature provides strong evidence for their molecular nature.

78.4 Concluding Remarks

The discovery of the $\chi_{c1}(3872)$ (also known as the $X(3872)$) in 2003 ushered in an era of tremendous progress in experimental heavy quark meson spectroscopy. As shown in Tables 78.1 to 78.3, more than 40 new states have been reported during this period, many of which were unanticipated. While the states below open-flavor thresholds (Table 78.1) appear to be well-explained by the conventional $q\bar{q}$ quark model, a thorough understanding of the suite of states above (Table 78.2) and near (Table 78.3) open-flavor thresholds remains elusive. After nearly two decades, experimental progress remains rapid with the continuation of BESIII, the commencement of the Belle II program, and the imminent accumulation of additional data at the LHC.

Acknowledgement

The authors would like to express their gratitude to Alex Bondar and Christoph Hanhart for productive discussions during the composition of this review.

79. Heavy Non-$q\bar{q}$ Mesons

Revised June 2021 by S. Eidelman (Budker Inst., Novosibirsk; Novosibirsk U.), T. Gutsche (Tübingen U.), C. Hanhart (Jülich) and R.E. Mitchell (Indiana U.).

The constituent quark model describes the observed meson spectrum as bound $q\bar{q}$ states grouped into SU(N) flavor multiplets (see the 'Quark Model' in this issue of the *Review of Particle Physics*). However, the self coupling of gluons in QCD suggests that additional mesons made of bound gluons (glueballs), or $q\bar{q}$-pairs with an excited gluon (hybrids), may exist. Furthermore, multiquark color singlet states such as $qq\overline{qq}$ (tetraquarks as compact diquark-antidiquark systems and 'molecular' bound states of two mesons) or $qqq\overline{qq}$ (six-quark, 'baryonium' or quasinuclear baryon-antibaryon bound states) have also been predicted. The focus of this review is on the current understanding of exotic states that apparently do not fit into the constituent quark model and contain at least one heavy quark (charm or bottom — the lifetime of the top quark is too short to allow it to hadronise). Light non-$q\bar{q}$ candidates (made of u, d and s quarks) are discussed in 'Spectroscopy of Light Meson Resonances' in this *Review*.

The review is split into 3 parts, discussing separately heavy–light systems, heavy–heavy systems, as well as systems with more than two heavy quarks. For a more detailed discussion of the experimental and/or theoretical status on exotic meson candidates in the doubly heavy meson sector we refer to Refs. [1–7]. Reviews with main focus on tetraquarks and molecular states are presented in Ref. [8] and in Ref. [9], respectively.

79.1 Heavy-light systems

Two very narrow states, $D_{s0}^*(2317)^\pm$ and $D_{s1}(2460)^\pm$, were observed at B factories [10, 11]. They lie far below the predicted masses for the two expected broad P-wave $c\bar{s}$ mesons. However, strong cusp effects, due to the nearby DK (DK^*) thresholds, could shift their masses downwards and quench the observed widths, still allowing for a conventional explanation of these states [12]. Such an effect was also claimed for the $a_0(980)$ and $f_0(980)$ mesons, which lie just below the $K\overline{K}$ threshold. In contrast to this picture, many authors favour exotic explanations for these lightest positive parity charmed states, such as four-quark states [13–16] or DK (DK^*) molecules [17–22]. Both states are isoscalars and thus the dominant open decay channels, $D_s^{(*)\pm}\pi^0$, lead to very small widths. For compact structures the hadronic decay is driven by $\eta - \pi^0$ mixing and one finds widths below 10 keV [12, 23]. In contrast to this a hadronic width of typically 100 keV would be the unequivocal signature for a prominent molecular nature of $D_{s0}^*(2317)^\pm$ [19, 21, 22, 24], since meson loops would then contribute significantly. The most refined analysis in the molecular scenario [24], where the parameters of the formalism are constrained by a large bulk of lattice QCD data on singly charmed systems, reports a prediction for the width in the range (104-116) keV. The currently measured upper bound for the width is 3.8 MeV.

It should be stressed that – akin to $q\bar{q}$ mesons – multiquark states also appear in multiplets. An important probe for the structure of hadrons is therefore the spectra, and in particular the SU(3) flavor multiplets within the different scenarios. For example the tetraquark model advocated in Refs. [16, 25] finds that the $D_{s0}^*(2317)^\pm$ should be degenerate with its non strange-partner state $D_0^*(2300)$ in line with the currently available experimental analyses. However, Ref. [26] showed that the recent LHCb data for $B \to D\pi\pi$ [27, 28] call for a significantly lighter lightest non-strange scalar charmed meson as soon as constraints from the chiral symmetry of QCD are employed in the analysis. This claim is in line with the recent lattice QCD study of Ref. [29]. In fact, the experimental as well as lattice data turn out to be consistent with the predictions from unitarised chiral perturbation theory pioneered for these systems in Ref. [18]. For more recent calculations see Refs. [24, 30, 31]. Moreover, all these latter calculations predict that there should be in addition a heavier flavor exotic state by about 300 MeV that indeed shows up in the above mentioned LHCb data [31]. Thus, in this picture the structure that appears as $D_0^*(2300)$ in the *Listings* originates from the interplay of two poles, similar to the $\Lambda(1405)$ in the baryon sector, see 'Pole structure of the $\Lambda(1405)$ region' in this *Review*. Two poles in the non-strange scalar sector are also generated in the tetraquark picture of Ref. [16], but in this work the real parts of the poles are located at 2308 MeV and 2666 MeV, in conflict with the data mentioned above. In the refined analysis of Ref. [25] it is shown, however, that the exact pole locations and even the ordering of the higher multiplets depend on the details of the model.

Manifestly exotic candidates around 2.9 GeV were reported in Refs. [32, 33] by LHCb in the $\bar{D}K$ system. Since the strong interactions preserve the quark flavor and the final state contains an $\bar{s}$ as well as a $\bar{c}$, color neutrality calls for a minimum quark content of $ud\bar{c}\bar{s}$. The explanation for those states include compact tetraquarks [34–36], hadronic molecules with a prominent $D^*\bar{K}^*$ component [37–39], or kinematic effects such as cusps or triangle singularities without nearby poles [40, 41]. The different pictures are contrasted and observable differences between them are discussed in Ref. [42].

79.2 Heavy-heavy systems

With the discovery of the $\chi_{c1}(3872)$[1] in $B^\pm \to K^\pm X$ ($X \to J/\psi\,\pi^+\pi^-$) by Belle [43] in 2003, soon confirmed by BaBar [44], many searches for states beyond the standard $q\bar{q}$ quark model were initiated in the charm and bottom sectors. For an updated collection of the currently available experimental information on multiquark states we refer to 'Spectroscopy of mesons containing two heavy quarks' in this *Review*, and in particular to Table 78.2. Moreover, in the decay $\Lambda_b^0 \to J/\psi\,K^-p$ the LHCb collaboration has recently reported the observation of new baryons decaying into $J/\psi(1S)\,p$, which are candidates for heavy pentaquark states [45,46]. They are discussed in some depth in 'Pentaquarks' in this *Review*.

When restricting ourselves to confirmed states we are faced with several states that do not seem to fit into the mass and quantum number schemes of basic $q\bar{q}$ quark models. This is clear for the five established charged states ($Z_c(3900)^\pm$, $Z_c(4020)^\pm$ [2], and $Z_c(4430)^\pm$ in the charmonium sector, and $Z_b(10610)^\pm$ and $Z_b(10650)^\pm$ in the bottomonium sector). The neutral states ($\chi_{c1}(3872)$, $\psi(4230)$, $\psi(4360)$, and $\psi(4660)$)[3] also challenge the quark model since their masses and decay properties are in conflict with expectations.

The quantum numbers of the $\chi_{c1}(3872)$ have been determined by LHCb to be $J^{PC} = 1^{++}$, first by assuming zero angular momentum between the $J/\psi(1S)$ and the dipion [47] and then by relaxing this constraint [48]. The $\chi_{c1}(3872)$ cannot be identified with the $\chi_{c1}(2^3P_1)$ since the latter is predicted to lie about 100 MeV higher in mass [49]. Instead, the $X(3940)$ reported by Belle in $e^+e^- \to J/\psi X$, decaying into $D^*\bar{D}$ but not into $D\bar{D}$ [50] could be the $\chi_{c1}(2^3P_1)$. The $\chi_{c2}(3930)$ 2^3P_2 tensor partner was reported by Belle at 3931 MeV in $\gamma\gamma$ interactions [51].

The $\chi_{c1}(3872)$ lies within 200 keV of the $D^0\bar{D}^{*0}$ threshold and its width is very small — recent Breit-Wigner analyses by LHCb [52,53] result in an average value of $\Gamma = (1.19 \pm 0.21)$ MeV as indicated in the *Listings*; employing the formalism of Ref. [54] under the constraint that the $D^*\bar{D}$ decay channel dominates, results in $\Gamma = 0.22^{+0.18}_{-0.19}$ MeV, where the standard convention is applied to use twice the imaginary part of the pole location as width. In the future those values can be refined more by either a direct measurement of the width that should be possible at the planned PANDA experiment [55, 56] or by exploiting the interplay of a triangle singularity and the $\chi_{c1}(3872)$ pole [57–59]. Therefore the most natural explanation for this state is a 1^{++} $D\bar{D}^*$ molecule [60], for which strong isospin breaking is predicted [60, 61], since the distance of the pole of the $\chi_{c1}(3872)$ to the $D^0\bar{D}^{*0}$ threshold is significantly smaller than to the D^+D^{*-} threshold. Indeed, the comparable rates for $\omega J/\psi$ and $\rho^0 J/\psi$ are

[1] The $\chi_{c1}(3872)$ is also known as the $X(3872)$. According to the PDG naming scheme, which we follow in this review, the primary name for a meson expresses its quantum numbers.

[2] While the $J^P = 1^+$ quantum numbers are plausible for this state, they are not yet established experimentally. This is why this state appears as $X(4020)$ in both the *Listings* and *Summary Tables*.

[3] The $\psi(4230)$, $\psi(4360)$, and $\psi(4660)$ are also known as the $Y(4230)$, $Y(4360)$, and $Y(4660)$, respectively. Before improved mass measurements, the $\psi(4230)$ was originally called the $\psi(4260)$ or $Y(4260)$.

consistent with an interpretation of $\chi_{c1}(3872)$ as an isoscalar $D\bar{D}^*$ molecule, when the different widths of the ρ and ω are taken into account [62]. Similarly, a dominant molecular $D^0\bar{D}^{*0}$ structure in the $\chi_{c1}(3872)$ with further subleading hadronic components is used to explain strong and radiative decays involving $J/\psi(1S)$ and $\psi(2S)$ in the final states [63, 64].

A four-quark state $cq\bar{c}\bar{q}'$ is another possible interpretation of the $\chi_{c1}(3872)$ [15] but a charged partner of the $\chi_{c1}(3872)$ has not been observed (e.g. not in $B^- \to \bar{K}^0 X^-$ nor in $B^0 \to K^+ X^-$, where $X^- \to J/\psi\,\pi^-\pi^0$ [65]) – see [66] for a possible explanation of this non-observation within the tetraquark approach assuming specific diquark correlations and the more recent discussion in Ref. [67]. The claim that $\chi_{c1}(3872)$ must be a compact (tetraquark) state, since it is also produced at very high p_T in $\bar{p}p$ collisions [68] and in high multiplicity final states [69], was challenged in [70] and [71], respectively, which in particular stress the importance of rescattering, see also Refs. [72, 73].

A broad structure, originally called $Y(4260)$, decaying into $J/\psi(1S)\,\pi^+\pi^-$ was reported by BaBar in initial state radiation $e^+e^- \to (\gamma_{\rm ISR})Y(4260)$ [74]. A subsequent measurement with significantly improved precision was reported by BESIII [75], and revealed that the original $Y(4260)$ cannot be described with a simple resonant lineshape. Fitting the BESIII data with two Breit-Wigner distributions leads to a narrower and lighter structure (referred to in the *Listings* as the $\psi(4230)$), but also requires a second state at 4320 MeV. However, note that the $D_1(2420)\bar{D}$ molecular model for the $\psi(4230)$ [76] can describe the same data with just one single pole [77]. How many vector states are in the mass range between 4220 MeV and 4400 MeV is not yet settled, but knowing this is crucial to allow for further progress.

There are no charmonium states expected in this mass region with quantum numbers 1^{--} from quark models using the Cornell type of interaction, although this might not be true for some screened versions thereof – for a recent discussion we refer to Ref. [78]. In addition, a charmonium state at this mass is expected to have significant couplings to one or more of the $\bar{D}^{(*)}D^{(*)}$ channels [79, 80], a feature that is not observed for the $\psi(4230)$. This state could be a hybrid charmonium with a spin-1 $\bar{c}c$ [81, 82] or a spin-0 [83, 84] core. However, provided that the observation of $\psi(4230)$ decay into $h_c(1P)\pi\pi$ by BESIII [85] is confirmed, the hybrid hypothesis would be under pressure, since the spin of the heavy quarks (coupled to zero in the $h_c(1P)$) should be conserved in leading order in the expansion in $(\Lambda_{\rm QCD}/m_c)$. (The individual conservation of the heavy quark spin and the total angular momentum of the light quark cloud is a consequence of the heavy-quark spin symmetry, see 'Heavy-Quark and Soft-Collinear Effective Theory' in this issue of the *Review*.) The same criticism applies to the hadrocharmonium interpretation of the $\psi(4230)$, which describes this state as spin-1 quarkonium surrounded by a light quark cloud [86]. To circumvent the spin-symmetry argument, Ref. [87] argues that $\psi(4230)$ and $\psi(4360)$ could be mixtures of two hadrocharmonia with spin-triplet and spin-singlet heavy quark pairs. The same kind of mixing could also be at work for hybrid structures.

A dominant $D_1(2420)\bar{D}$ component in the $\psi(4230)$ [88] explains naturally why $Z_c(3900)^\pm$ (interpreted by the authors as a $\bar{D}D^*$ bound state) is seen in $\psi(4230) \to \pi^\mp Z_c(3900)^\pm$. A similar mechanism is also found in Ref. [89] linking in addition the $J/\psi(1S)\pi^+\pi^-$ and $\psi(2S)\pi^+\pi^-$ decays of the $\psi(4230)$. Furthermore, a copious production of $\chi_{c1}(3872)$ in $\psi(4230)$ radiative decays was predicted from the prominent $D_1\bar{D}$ component of the $\psi(4230)$ [90], which was confirmed by BESIII [91]. Possible charmonia components both in $\psi(4230)$ and $\chi_{c1}(3872)$ can influence the radiative transition but they are shown to be of subleading order [92]. The $\psi(4360)$ as a $D_1\bar{D}^*$ bound state could be the spin partner of the $\psi(4230)$ [93, 94], but a detailed microscopic calculation is still lacking.

The tetraquark picture calls for four ground state vector states — once the parameters of the model are fixed from some candidate states in the negative and positive parity sector, states with other quantum numbers can be predicted. Possible scenarios are for instance discussed in Ref. [95] which builds on a tailor-made spin-spin interaction [96] to describe the $\chi_{c1}(3872)$, both $Z_c(3900)^{\pm,0}$ and $Z_c(4020)^\pm$ and even the $Z(4430)^\pm$ confirmed by Belle [97] and LHCb [98]. This model also explains the copious production of $\chi_{c1}(3872)$ in $\psi(4230)$ radiative decays mentioned above [96, 99]. However, tetraquark models (in most cases based on diquark-antidiquark configurations) tend to predict many additional charged and neutral states which have not yet been discovered. In particular, as for the conventional $\bar{q}q$ structures one should expect nearly degenerate isoscalar and isovector states in analogy to the near degeneracy of $\rho(770)$ and $\omega(782)$. The problem and possible explanations are discussed in some detail in Refs. [66, 67].

Ref. [100] found a sizeable SU(3) flavor octet contribution when analysing the $\pi\pi$ final state from $\psi(4230) \to J/\psi(1S)\pi^+\pi^-$, which is consistent with both a molecular and a tetraquark interpretation of $\psi(4230)$, but at odds with a hybrid or a $\bar{c}c$ interpretation.

In the mass range above 4600 MeV, the number of poles is also not yet settled. Experimental signals are seen in the $\psi(2S)\pi\pi$, $\Lambda_c^+\bar{\Lambda}_c^-$ and $D_s\bar{D}_{s1}$ final states. In the *Listings* the former two structures go into one node, $\psi(4660)$ due to their proximity in parameter values. Moreover, various theoretical works describe these states in a combined analysis [101–103]. The signal in the hidden strangeness mode around 4630 MeV still calls for confirmation and might be yet another realisation of the same state, but there are already speculations about its nature. While Ref. [104] argues in favor of a $D_s^{(*)}\bar{D}_{s1}(2536)$ or $D_s^{(*)}\bar{D}_{s2}(2573)$ [105] molecular nature, Ref. [106] does not confirm these claims. Ref. [107] identifies the structure as P-wave $[cs][\bar{c}\bar{s}]$ tetraquark state. Other explanations of the $\psi(4660)$ include a $\psi(2S)f_0(980)$ molecule [108] and a $\Lambda_c^+\bar{\Lambda}_c^-$ baryonium [101]. Also in this mass range studies of the partner states, driven either by spin or flavor symmetry will be very valuable — see e.g. the predictions in Ref. [109].

The isovector states $Z_c(3900)$ and $Z_c(4020)$, first observed by BESIII [110, 111], decay predominantly into $\bar{D}D^*$ and $\bar{D}^*D^*$, respectively, while the $Z_b(10610)$ and $Z_b(10650)$, first observed by Belle [112, 113], decay predominantly into $\bar{B}B^*$ and $\bar{B}^*B^*$ [114], respectively, although all four were discovered in the decay mode heavy quarkonium plus pion. This suggests that these states are close relatives and their interactions are connected via heavy quark flavor symmetry. A molecular interpretation for the bottomonium states was proposed shortly after the discovery of the two Z_b states [115] and also shortly after that of the $Z_c(3900)$ [88]. This picture is confirmed within the meson exchange model of Ref. [116]. Decay patterns of $Z_c(3900)$ and the two Z_b were also shown to be consistent with a molecular interpretation [117–119]. However, some of their properties also appear to be consistent with tetraquark structures [120]. If the molecular picture were correct for the Z_b states, spin symmetry would lead to the existence of spin partner states [121–123], which are still to be found. In Ref. [124] it was shown that the actual pole locations of these partner states would be good probes of one-pion exchange in the molecular potential, which makes the experimental search for those states even more interesting.

The heaviest confirmed charged state in the charmonium sector is the $Z(4430)^\pm$ observed by Belle [97]. It is interpreted as hadrocharmonium [86], $\bar{D}_1D^*$ molecule [125], as well as tetraquark [96]. Alternatively, in [126, 127] the $Z(4430)^\pm$ is explained as a cross-channel effect enhanced by a triangle singularity from open charm states. These works were criticised in Ref. [128] where an alternative triangle consisting of a K^*, a π, and the $\psi(4230)$, is proposed to generate the $Z_c(4430)$. The Argand diagram shows an anticlockwise circle, in line with the experimental analysis [98], while the one of Ref. [127] shows a clockwise motion. By replacing the $\psi(4230)$ by the $\psi(3770)$ and changing the K^* one can also interpret the $Z_c(4200)$ as a kinematic effect [128]. A possible interpretation of $Z_c(3900)$ and $Z_c(4020)$ as crossed channel effects is put forward in Ref. [129]. It remains to be seen, however, if this kind of explanation is also capable of explaining the observations of these lowest Z_c states, also at other total energies.

There is recent evidence for a charged charmonium-like state with strangeness, $Z_{cs}(3985)$, from BESIII [130]. The possible existence of a strange partner to the Z_c near the $D_s\bar{D}^*$ thresholds has been predicted in molecular models [131, 132], for

tetraquarks [133,134], for hadrocharmonium structures [134,135], and as a coupled-channel effect [136]. Later on this state is interpreted in Refs. [137,138] as a member of the same multiquark octet and in Refs. [139,140] as a member of the same molecular one as the $Z_c(3900)$. Ref. [138] is also able to describe the recent LHCb data in the $J/\psi(1S)K^-$ system [141], although the extracted total width for their lowest Z_{cs} state is an order of magnitude larger than that found by BESIII. Refs. [142, 143] claim that both the molecular components and the compact tetraquark core are relevant to describe the $Z_c(3900)$ and $Z_{cs}(3985)$ resonances. Again, in [144] the $Z_{cs}(3985)$ can be explained as a coupled-channel effect producing the enhancement close to threshold.

It should be stressed that the various scenarios, while describing much of the available data, also make decisive predictions, *e.g.* yet unobserved quantum numbers [95,145]. The forthcoming data on heavy meson spectroscopy from various facilities should provide a much deeper understanding of how QCD forms matter out of quarks and gluons.

There is a very recent report by LHCb [146] on the observation of a narrow peak in the $D^0D^0\pi^+$ invariant mass distribution just below the $D^{*+}D^0$ threshold. This structure would possess a minimal $cc\bar{u}\bar{d}$ quark content. An assessment of this state will be discussed in the next issue of this review.

79.3 Systems containing four heavy quarks

Recently LHCb reported the observation of pronounced structures in a double-$J/\psi(1S)$ invariant mass distribution [147] thus pointing at states with $cc\bar{c}\bar{c}$ quarks contents. From quark models the possible existence of bound states like this was discussed already long ago [148,149]. There are now also many model calculations available in the literature. For discussions of those data from the compact tetraquark perspective see Refs. [150–156]. Most of these quark model calculations assign the reported structure to a $cc\bar{c}\bar{c}$ state in the $2S$ multiplet with near-degenerate $J^P = 0^+$, 1^+ and 2^+ configurations. The dominance of a compact tetraquark component in the apparently exotic structure is also supported by the coupled multichannel study of Ref. [157]. For direct analyses of the data within the tetraquark approach, see, e.g., Ref. [158]. Also QCD sum rule studies of the system were published, but do not give consistent results: For example Ref. [159] interprets the structure at 6900 MeV as a hybrid state, Ref. [160] as a tetraquark, and Ref. [161] states that both molecular and tetraquark interpretations are possible. An alternative view on the LHCb double-$J/\psi(1S)$ data is provided in Refs. [162–164] where the analyses are performed using coupled channel T-matrices. In both works the structures in the data emerge from the interplay of thresholds and resonances with the non-trivial prediction that there should exist, if this dynamical picture were correct, a state located very near the double-$J/\psi(1S)$ threshold which can be searched for experimentally.

In contrast to the works above, Ref. [165, 166] explains the double-$J/\psi(1S)$ data as cusps without nearby poles. This claim can be tested experimentally: if this explanation were correct, there should not be any narrow near threshold structure in the channel that generates the cusp, for that would call for a non-perturbative interaction in that channel as pointed out in Ref. [167].

Acknowledgement

The authors would like to thank Claude Amsler and Jean-Marc Richard for helpful input and discussions in the preparation of the review.

80. Baryon Decay Parameters

Revised August 2019 by E.D. Commins (UC Berkeley).

80.1 Baryon semileptonic decays

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written as:

$$\overline{B}_f \left[f_1(q^2)\gamma_\lambda + i\, f_2(q^2)\sigma_{\lambda\mu}q^\mu + g_1(q^2)\gamma_\lambda\gamma_5 + g_3(q^2)\gamma_5 q_\lambda \right] B_i \ . \tag{80.1}$$

Here B_i and $\overline{B}_f$ are spinors describing the initial and final baryons, and $q = p_i - p_f$, while the terms in f_1, f_2, g_1, and g_3 account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V, and g_1 reduces to the axial-vector coupling constant g_A. The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an $e^\pm$ is emitted, and gives a very small correction, which can be estimated by PCAC [4], for $\mu^\pm$ modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f} \ , \tag{80.2}$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. [6] in the Listings for neutron beta decay. For comparison with experiments at higher q^2, it is necessary to modify the form factors at $q^2 = 0$ by a "dipole" q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio g_A/g_V may be written as

$$g_A/g_V = |\, g_A/g_V \,| \, e^{i\phi_{AV}} \ . \tag{80.3}$$

The presence of a "triple correlation" term in the transition probability, proportional to $\mathrm{Im}(g_A/g_V)$ and of the form

$$\boldsymbol{\sigma_i \cdot (p_\ell \times p_\nu)} \tag{80.4}$$

for initial baryon polarization or

$$\boldsymbol{\sigma_f \cdot (p_\ell \times p_\nu)} \tag{80.5}$$

for final baryon polarization, would indicate failure of time-reversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ^{19}Ne nuclear beta decay), and the results are consistent with T invariance.

80.2 Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F\, m_\pi^2 \cdot \overline{B}_f \,(A - B\gamma_5)\, B_i \ , \tag{80.6}$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma\, \widehat{\boldsymbol{\omega}}_f \cdot \widehat{\boldsymbol{\omega}}_i + (1-\gamma)(\widehat{\boldsymbol{\omega}}_f \cdot \widehat{\mathbf{n}})(\widehat{\boldsymbol{\omega}}_i \cdot \widehat{\mathbf{n}}) + \alpha(\widehat{\boldsymbol{\omega}}_f \cdot \widehat{\mathbf{n}} + \widehat{\boldsymbol{\omega}}_i \cdot \widehat{\mathbf{n}}) + \beta \widehat{\mathbf{n}} \cdot (\widehat{\boldsymbol{\omega}}_f \times \widehat{\boldsymbol{\omega}}_i) \ , \tag{80.7}$$

where $\widehat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\widehat{\boldsymbol{\omega}}_i$ and $\widehat{\boldsymbol{\omega}}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α, β, and γ are defined as

$$\begin{aligned} \alpha &= 2\,\mathrm{Re}(s^* p)/(|\, s\,|^2 + |\, p\,|^2) \ , \\ \beta &= 2\,\mathrm{Im}(s^* p)/(|\, s\,|^2 + |\, p\,|^2) \ , \\ \gamma &= (|\, s\,|^2 - |\, p\,|^2)/(|\, s\,|^2 + |\, p\,|^2) \ , \end{aligned} \tag{80.8}$$

where $s = A$ and $p = |\, \mathbf{p}_f \,| B/(E_f + m_f)$; here E_f and $\mathbf{p}_f$ are the energy and momentum of the final baryon. The parameters α, β, and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1 \tag{80.9}$$

If the hyperon polarization is $\mathbf{P}_Y$, the polarization $\mathbf{P}_B$ of the decay baryons is

$$\mathbf{P}_B = \frac{(\alpha + \mathbf{P}_Y \cdot \widehat{\mathbf{n}})\widehat{\mathbf{n}} + \beta(\mathbf{P}_Y \times \widehat{\mathbf{n}}) + \gamma \widehat{\mathbf{n}} \times (\mathbf{P}_Y \times \widehat{\mathbf{n}})}{1 + \alpha \mathbf{P}_Y \cdot \widehat{\mathbf{n}}} \ . \tag{80.10}$$

Here $\mathbf{P}_B$ is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\widehat{\mathbf{n}}$ from the hyperon rest frame, in which $\widehat{\mathbf{n}}$ and $\mathbf{P}_Y$ are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin\!\phi \ . \tag{80.11}$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α, ϕ, and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta = 0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |\, s\,| \, e^{i\delta_s} \ \text{and} \ p = |\, p\,| \, e^{i\delta_p} \ , \tag{80.12}$$

where δ_s and δ_p are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2\,|\, s\,|\,|\, p\,|}{|\, s\,|^2 + |\, p\,|^2} \sin(\delta_s - \delta_p) \ . \tag{80.13}$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \to p\pi^-$ decay, the value of Δ may be compared with the s- and p-wave phase shifts in low-energy $\pi^- p$ scattering, and the results are consistent with T invariance.

81. N and Δ Resonances

Revised August 2019 by V.D. Burkert (Jefferson Lab), V. Crede (Florida State U.), U. Thoma (Bonn U.), L. Tiator (KPH, JGU Mainz) and R.L. Workman (George Washington U.).

81.1 Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. Until recently, the Breit-Wigner masses and widths, the pole positions, and the elasticities of the N and Δ resonances in the Baryon Summary Table came largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. The most comprehensive analyses were carried out by the Karlsruhe-Helsinki (KH80) [1], Carnegie Mellon-Berkeley (CMB80) [2], and George Washington U (GWU) [3] groups. Partial-wave analyses have also been performed on much smaller πN reaction data sets to get ηN, $K\Lambda$, and $K\Sigma$ branching fractions (see the Listings for references). Other branching fractions come from analyses of $\pi N \to \pi\pi N$ data.

In recent years, a large amount of data on photoproduction of many final states has been accumulated, and these data are beginning to tell us much about the properties of baryon resonances. A survey of data on photoproduction can be found in the proceedings of recent conferences [4] and workshops [5], and in recent reviews [6, 7].

81.2 Naming scheme for baryon resonances

In the past, when nearly all resonance information came from elastic πN scattering, it was common to label resonances with the incoming partial wave $L_{2I,2J}$, as in $\Delta(1232)P_{33}$ and $N(1680)F_{15}$. However, most recent information has come from γN experiments. Therefore, we have replaced $L_{2I,2J}$ with the spin-parity J^P of the state, as in $\Delta(1232)3/2^+$ and $N(1680)5/2^+$; this name gives intrinsic properties of the resonance that are independent of the specific particles and reactions used to study them. This applies equally to all baryons, including Ξ resonances and charm baryons that are not produced in formation experiments. We do not, however, attach the mass or spin-parity to the names of the ground-state ("stable") baryons $N, \Lambda, \Sigma, \Xi, \Omega, \Lambda_c, \cdots$.

81.3 Using the N and Δ listings

Tables 81.1 and 81.2 list all the N and Δ entries in the Baryon Listings and give our evaluation of the overall status and the status channel by channel. Only the established resonances (overall status 3 or 4 stars) are promoted to the Baryon Summary Table. We long ago omitted from the Listings information from old analyses, prior to KH80 and CMB80, which can be found in earlier editions. A rather complete survey of older results was given in our 1982 edition [8].

As a rule, we award an overall status **** or *** only to those resonances which are derived from analyses of data sets that include precision differential cross sections and polarization observables, and are confirmed by independent analyses. All other signals are given ** or * status. New results that are not accompanied by proper error evaluation are less valuable for evaluating star ratings. The following criteria are guidelines for future error analysis.

1. Uncertainties in resonance parameters: The publication should have a detailed discussion on how the uncertainties of parameters were estimated. This requires that the error estimates go beyond the simple fit error as e.g. given by MINUIT, and the robustness of the results should be demonstrated.

2. Fit quality: Concrete measures for the fit quality should be provided. The reduced global χ^2 value of the fit, while useful, is insufficient. Other possibilities include quoting variations of local χ^2 values in kinematic regions where evidence for new resonances, or significantly improved information on resonance parameters, is claimed.

3. Weight factors in observables: Analyses sometimes use weight factors for certain data sets to either increase or reduce their impact on the results. This has been particularly important when polarization observables are involved, which often are sensitive to resonance amplitudes through interferences, but usually have much poorer statistics than differential cross section data. To evaluate sensitivities, the resulting resonance parameters should be checked against variations of the specific weight factors.

Table 81.1: The status of the N resonances and their decays. Sub-threshold decay modes are omitted. Only resonances with an overall status of *** or **** are included in the main Baryon Summary Table.

Claims of evidence for new baryon states must be based on a sufficiently complete set of partial waves in the fit. The robustness of signals must be demonstrated, e.g. by examining the effect of

higher partial waves in the fit.

81.4 Properties of resonances

Resonances are defined by poles of the S-matrix, whether in scattering, production or decay matrix elements. These are poles in the complex plane in s, as discussed in the new review on *Resonances*. As is traditional, we quote here the pole positions in the complex energy $w = \sqrt{s}$ plane. Crucially, the position of the pole of the S-matrix is independent of the process, and the production and decay properties factorize. This is the rationale for listing the pole position first for each resonance. These key properties of the S-matrix pole are in contrast to other quantities related to resonance phenomena, such as Breit-Wigner parameters or any K-matrix pole. Breit-Wigner parameters depend on the formalism used, such as angular-momentum barrier factors, or cut-off parameters, and the assumed or modeled background. However, the accurate determination of pole parameters from the analysis of data on the real energy axis is not necessarily simple, or even straightforward. It requires the implementation of the correct analytic structure of the relevant (often coupled) channels.

In principle, there are two ways to extract pole parameters from experimental data: (i) analytic continuation of theoretical single- or multi-channel models into the complex energy plane or (ii) local expansions of the partial-wave T-matrix amplitudes in the complex energy plane in the vicinity of a pole.

At present, poles are usually extracted using the first method [9–14], but considerable effort has been put into the development of alternate approaches, such as the speed plot [15], time delay [16], N/D method [17], regularization procedure [18], or Padè approximation [19].

Methods of the second type are based on the idea to use first or higher-order derivatives in energy to reduce the importance of, or totally eliminate, the background contribution. One either has to model the background contribution and introduce model dependence, or one is faced with numerical derivatives of single-energy data. In both cases, one reaches almost unsurmountable difficulties.

An alternate way to extract pole parameters from partial waves has been proposed by introducing a Laurent+Pietarinen (L+P) expansion [20–22]

$$T(W) = \sum_{i=1}^{N} \frac{Res_i}{W - W_i} + \sum_{j=1}^{M} \sum_{n=0}^{n_{max}} c_n^j \left(\frac{\alpha_j - \sqrt{x_j - W}}{\alpha_j + \sqrt{x_j - W}}\right)^n , \quad (81.1)$$

where $T(W)$ is a given partial wave amplitude, W_i and Res_i are the N complex pole positions and residues. The background is parameterized with M Pietarinen functions, where α_j are positive range parameters and x_j are real or complex branch points; c_n^j are real expansion coefficients.

The main idea of this procedure is to find the simplest analytic function, with well-defined poles and cuts, regardless of whether they are generated by a theoretical model or some energy-independent procedure. Instead of searching for the function which reproduces the input amplitudes over the complete complex energy plane, on all Riemann sheets, a representation is searched only in a limited complex energy range, near the real axis, which is defined by the radius of convergence of the Laurent decomposition, and which contains the input amplitudes. All details are found in Ref. [21]. Applications of the method can be found in [20–27].

81.5 Photoproduction

A new approach to the nucleon excitation spectrum is provided by dedicated facilities at the Universities of Bonn, Grenoble, and Mainz, and at the national laboratories Jefferson Lab in the US and SPring-8 in Japan. High-precision cross sections and polarization observables for the photoproduction of pseudoscalar mesons provide a data set that is approaching a "complete experiment," one that fully constrains the four complex amplitudes describing the spin-structure of the reaction [28]. A large number of photoproduction reactions has been studied.

In pseudoscalar meson photoproduction, the four independent helicity amplitudes can be expressed in terms of the four CGLN [29] amplitudes allowed by Lorentz and gauge invariance. These amplitudes can be expanded in a series of electric and magnetic multipoles. Except for $J = 1/2$, one electric and one magnetic multipole contributes to each J^P combination.

For a given state, these two amplitudes determine the resonance photo-decay helicity amplitudes $A_{1/2}$ and $A_{3/2}$. As described below, this resonance extraction has been carried out either assuming a Breit-Wigner resonance or at the pole.

If a Breit-Wigner parametrization is used, the $N\gamma$ partial width, Γ_γ, is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_\gamma = \frac{k_{\rm BW}^2}{\pi} \frac{2m_N}{(2J+1)m_{\rm BW}} \left(|A_{1/2}|^2 + |A_{3/2}|^2 \right) . \quad (81.2)$$

Here m_N and $m_{\rm BW}$ are the nucleon and resonance masses, J is the resonance spin, and $k_{\rm BW}$ is the photon c.m. decay momentum. Most earlier analyses have provided these real quantities $A_{1/2}$ and $A_{3/2}$.

More recent studies have quoted related complex quantities, evaluated at the T-matrix pole. These complex helicity amplitudes, $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$, can be cast onto the form

$$\tilde{A}_h = \sqrt{\frac{\pi(2J+1)w_{\rm pole}}{m_N k_{\rm pole}^2}} \frac{Res(T_h(\gamma N \to N\, b))}{\sqrt{Res(T\,(N\, b \to N\, b))}} \quad (81.3)$$

where the residues (Res) are evaluated at the pole position, $w_{\rm pole}$, and $k_{\rm pole}^2 = (w_{\rm pole}^2 - m_N^2)^2/4w_{\rm pole}^2$ [30]. For Breit-Wigner amplitudes, $w_{\rm pole} = m_{\rm BW}$ and $\tilde{A}_h = A_h$. Similar relations for the photo and electro couplings at the pole position can be found in [31,32].

The determination of eight real numbers from four complex amplitudes (with one overall phase undetermined) requires at least seven independent measurements. At least one further measurement is required to resolve discrete ambiguities that result from the fact that data are proportional to squared amplitudes. Photon beams and nucleon targets can be polarized (with linear or circular polarization $P_\perp$, $P_\odot$ and $\vec{T}$, respectively); the recoil polarization of the outgoing baryon $\vec{R}$ can be measured. The experiments can be divided into three classes: (1) the beam and target are polarized (BT); (2) the beam is polarized and the recoil baryon polarization is measured (BR); (3) the target is polarized and the recoil polarization is measured (TR). Different sign conventions are used in the literature, as summarized in [33].

One of the best studied reactions is $\gamma p \to \Lambda K^+$. Published data include differential cross sections, the beam asymmetry Σ, the target asymmetry T, the recoil polarization P, and the BR double-polarization variables $C_{x'}, C_{z'}, O_{x'}$, and $O_{z'}$. For the photoproduction of pions and etas, off proton and neutron targets, differential cross sections, single- and double-polarization asymmetries have been measured, mainly for pions.

81.6 Electroproduction

Electroproduction of mesons provides information on the internal structure of resonances. The helicity amplitudes are functions of the (squared) momentum transfer $Q^2 = -(e-e')^2$, where e and e' are the 4-momenta of the incident and scattered electron, and a third amplitude, $S_{1/2}$, measures the resonance response to the longitudinal component of the virtual photon. Most data stem from the reactions $e^- p \to e^- n\pi^+$ and $e^- p \to e^- p\pi^0$ but also the reactions $e^- p \to e^- p\eta$, $e^- p \to e^- p\pi^+\pi^-$, and $e^- p \to e^- \Lambda(\Sigma^0)K^+$ have been studied. The data and their interpretation are reviewed in Refs. [34,35].

The transition to the $\Delta(1232)3/2^+$ is often quantified in terms of the magnetic dipole transition moment M_{1+} (or the magnetic transition form factor $G^*_{M,Ash}(Q^2)$) [36], and the electric and scalar quadrupole transition moments E_{1+} and S_{1+}. Figure 81.1 shows the strength of the $p \to \Delta^+$ transition plotted versus the photon virtuality Q^2. At $Q^2 = 0$, M_{1+} dominates the resonance transition strength. The two amplitudes E_{1+} and S_{1+} imply a quadrupole deformation of the transition to the lowest excited state. The magnitude of $R_{EM} = E_{1+}/M_{1+}$ remains nearly constant, while the magnitude of $R_{SM} = S_{1+}/M_{1+}$ increases rapidly up to 25% at the highest Q^2 value.

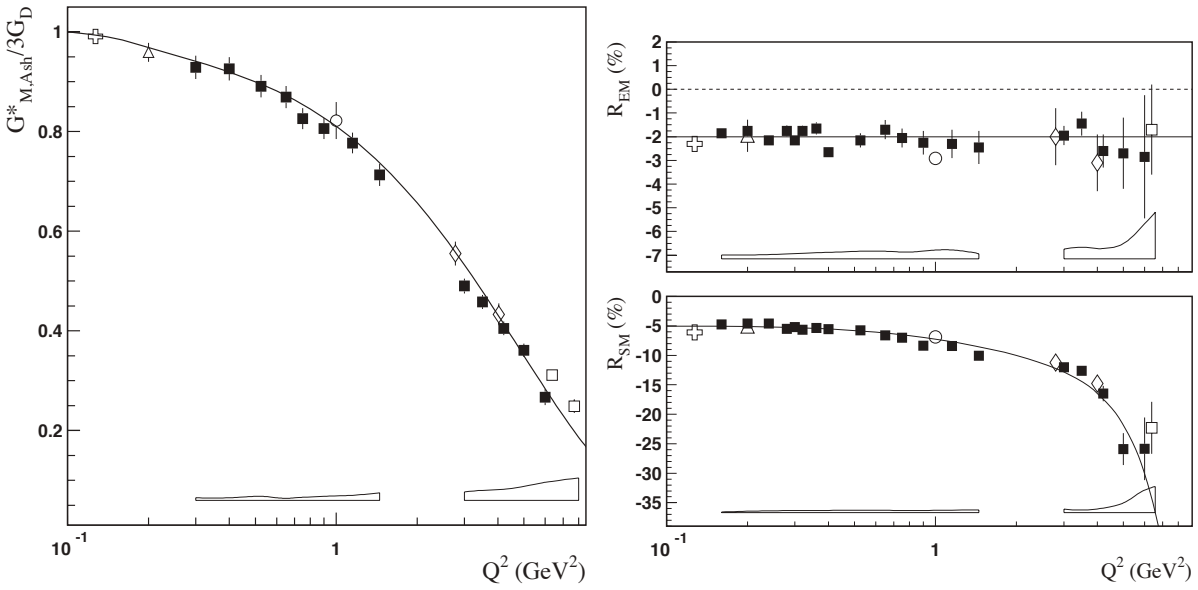

Figure 81.1: Left: The magnetic transition form factor for the $\gamma^* p \to \Delta^+(1232)$ transition versus the photon virtuality Q^2. Right: The electric and scalar quadrupole ratios R_{EM} and R_{SM}. The different symbols are results from different experiments at JLab (squares, diamonds, circle) and MAMI (triangle, cross). The boxes near the horizontal axis indicate model uncertainties of the squares. Curves to guide the eyes.

Figure 81.2 shows the transverse and scalar helicity amplitudes for the $N(1440)1/2^+$, $N(1520)3/2^-$, and $N(1535)1/2^-$ resonances from JLab [34]. Similar results have been achieved at Mainz [35]. For the states $N(1440)1/2^+$ and $N(1520)3/2^-$, helicity amplitudes and $\pi\Delta$ and ρp decays were determined at JLab in an analysis of $\pi^+\pi^- p$ electroproduction [37]. The data show distinctly different Q^2 dependencies that indicate different internal structures.

The $N(1520)3/2^-$ helicity amplitudes reveal the dominance of its three-quark nature: the $A_{3/2}$ amplitude is large at the photon point and decreases rapidly $\sim Q^{-5}$ with increasing Q^2; $A_{1/2}$ is small at the photon point, increases rapidly with Q^2 and then falls off with $\sim Q^{-3}$. Quantitative agreement with the data is, however, achieved only when meson cloud effects are included.

At high Q^2, both amplitudes for $N(1440)1/2^+$ are qualitatively described by light front quark models [38]: at short distances the resonance behaves as expected from a radial excitation of the nucleon. On the other hand, $A_{1/2}$ changes sign at about $0.6\,\mathrm{GeV}^2$. This remarkable behavior has not been observed before for any nucleon form factor or transition amplitude. Obviously, an important change in the structure occurs when the resonance is probed as a function of Q^2.

The Q^2 dependence of $A_{1/2}$ of the $N(1535)1/2^-$ resonance exhibits the expected Q^{-3} dependence, except for small Q^2 values where meson cloud effects set in.

Figure 81.3 shows the transverse and scalar amplitudes for three states in the 3rd nucleon resonance region, the $\Delta(1620)1/2^-$, the $N(1675)5/2^-$ and $N(1680)5/2^+$. The latter two states have nearly degenerate masses and are parity partners. In the quark model picture, the transverse amplitudes for $N(1675)5/2^-$ on the proton are suppressed due to the Moorhouse selection rule, allowing for a quantitative evaluation of the meson-baryon contributions. The data show significant meson-baryon strength in the $A_{1/2}$ amplitude even at quite high Q^2, while $A_{3/2}$ drops much faster with Q^2. $N(1680)5/2^+$ shows qualitatively the features predicted in constituent quark models, a dominant $A_{3/2}$ at the real photon point that drops rapidly with increasing Q^2, while $A_{1/2}$ becomes the dominant contribution at high Q^2, indicating a switch of the helicity structure in the resonance transition at short distances.

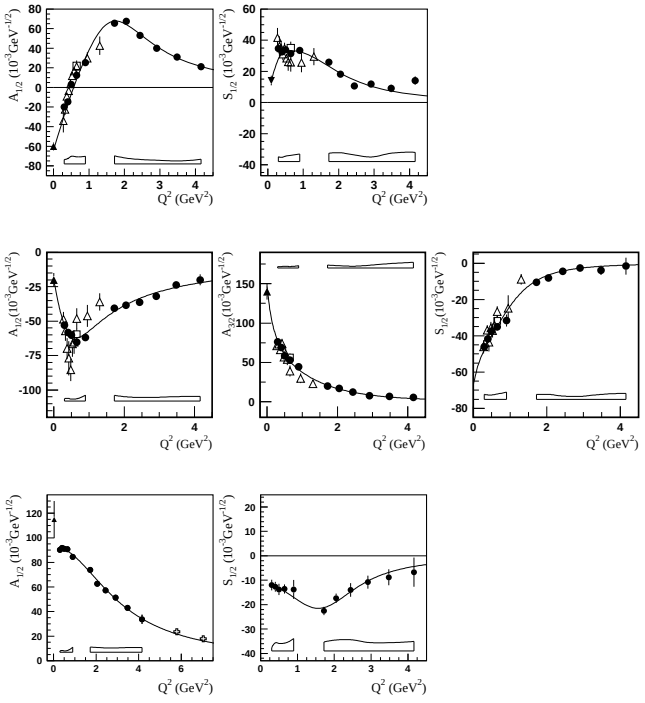

Figure 81.2: Transverse and scalar (longitudinal) helicity amplitudes for $\gamma p \to N(1440)1/2^+$ (top), $\gamma p \to N(1520)3/2^-$ (center), and $\gamma p \to N(1535)1/2^-$ (bottom) as extracted from the JLab/-CLAS data in $n\pi^+$ production (full circles), MAMI/A1 data in $p\pi^0$ production (full down triangle), in $p\pi^+\pi^-$ (open triangles), and combined single and double pion production (open squares). The solid triangle is the PDG 2014 value at $Q^2 = 0$. The open boxes are the model uncertainties of the full circles.

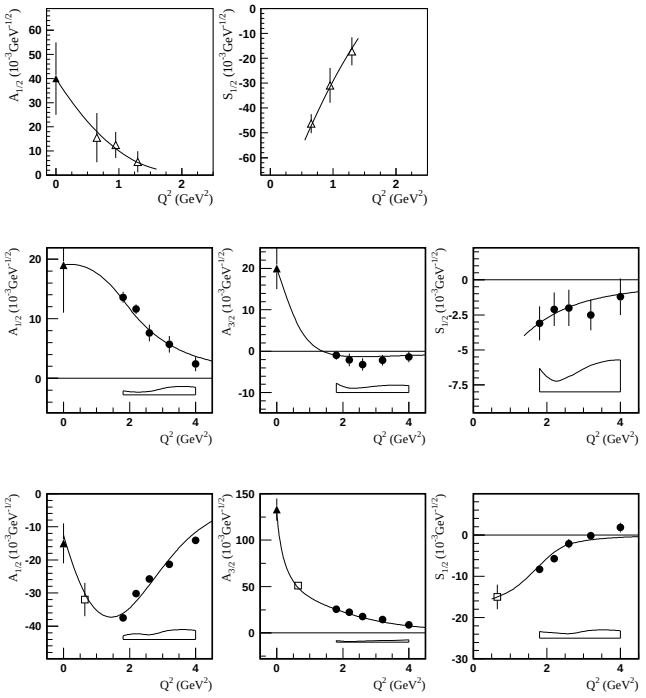

Figure 81.3: Transverse and scalar helicity amplitudes for $\gamma p \to \Delta(1620)1/2^-$ (top), $\gamma p \to N(1675)5/2^-$ (center), and $\gamma p \to N(1680)5/2^+$ (bottom) as extracted from the JLab/CLAS data in $n\pi^+$ production (full circles), $p\pi^+\pi^-$ (open triangles), combined single and double pion production (open square). The solid triangle is the 2014 PDG value at $Q^2 = 0$. The open boxes are the model uncertainties of the full circles. The curves are to guide the eye.

81.7 Partial wave analyses

Several PWA groups are now actively involved in the analysis of the new data. The GWU group maintains a nearly complete database covering reactions from πN and KN elastic scattering to $\gamma N \to N\pi$, $N\eta$, and $N\eta'$. It is presently the only group determining πN elastic amplitudes from scattering data in sliced energy bins. Given the high-precision of photoproduction data already or soon to be collected, the spectrum of N and Δ resonances will in the near future be better known.

Fits to the data are performed by various groups with the aim to understand the reaction dynamics and to identify N and Δ resonances. For practical reasons, approximations have to be made. We mention several analyses here: (1) The Mainz unitary isobar model [39] focuses on the correct treatment of the low-energy domain. Resonances are added to the unitary amplitude as a sum of Breit-Wigner amplitudes. This model also obtains resonance transition form factors and helicity amplitudes from electroproduction [35]. (2) For $N\pi$ electroproduction, the Yerevan/JLab group uses both the unitary isobar model and the dispersion relation approach developed in [38]. A phenomenological model was developed to extract resonance couplings and partial decay widths from exclusive $\pi^+\pi^- p$ electroproduction [37]. (3) Multichannel analyses using K-matrix parameterizations derive background terms from a chiral Lagrangian - providing a microscopical description of the background - (Giessen [40, 41]) or from phenomenology (KSU [42, 43], Bonn-Gatchina [44]). (4.) Several groups (EBAC-Jlab [45, 46], ANL-Osaka [47], Dubna-Mainz-Taipeh [48], Bonn-Jülich [49–51], Valencia [52]) use dynamical reaction models, driven by chiral Lagrangians, which take dispersive parts of intermediate states into account. Several other groups have made important contributions. The Giessen group pioneered multichannel analyses of large data sets on pion- and photo-induced reactions [40, 41]. The Bonn-Gatchina group included recent high-statistics data and reported systematic searches for new baryon resonances in all relevant partial waves. A summary of their results can be found in [44].

82. Λ and Σ Resonances

Revised August 2021 by V.D. Burkert (Jefferson Lab), V. Crede (Florida State U.), E. Klempt (Bonn U.), U. Thoma (Bonn U.), L. Tiator (KPH, JGU Mainz) and R.L. Workman (George Washington U.).

82.1 Introduction

For several decades, there has been very little new experimental data bearing on the properties of Λ and Σ resonances. An exception was the study at JLab of the reactions $\gamma p \to K^+\Sigma^\pm\pi^\mp$ and $\gamma p \to K^+\Sigma^0\pi^0$ [1], which established the spin and parity of the $\Lambda(1405)$ [2]. There was also from BNL new data on the very low energy region of K^-p scattering [3–7]. Otherwise, the field is starved for data. Recent analyses (see below) have improved what we know about the *properties* of the known Λ and Σ resonances, but the *established* resonances are the same ones that were listed in our 1984 edition [8] except for the $\Sigma(2250)$ which we consider 2-star only due to its unkown spin-parity. The 1990 Review [9] gave a full report of the status of Lambda and Sigma hyperons, and included Argand plots from the partial-wave analyses. The 2018 Review [10] has a short survey of the $\Sigma(1670)$-region.

In the last few years, four groups have re-analyzed K^-p reactions using more extensive collections of the old data. These analyses justify an update of the status of the Λ and Σ resonances. Although they have not established any new resonances, they have provided at least some evidence for new states and have given a better understanding of the old ones.

Tables 82.1 and 82.2 give our evaluation of the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. In making these evaluations, we considered, in addition to the four analyses [11–14], the ratings that predated them. The ratings use a 1- to 4-star system. For more details on the evaluation of the overall star ratings, see [15]. The main Summary Table includes only established states with an overall status of 3 or 4 stars; as has already been noted, these are the same fourteen Λ resonances (including $\Lambda(1116)$) and nine Σ resonances instead of the former ten (including $\Sigma(1193)3/2^+$, and $\Sigma(1385)3/2^+$) that had long been in the Table. In addition, there are seven 1-star and two 2-star Λ's, and fourteen 1-star and three 2-star Σ's in the Particle Listings.

82.2 New analyses

The new analysis progress was pioneered by the Kent group which collected a large fraction of the available data and performed a comprehensive partial wave analysis [11,16]. K^-p scattering into a pseudoscalar meson and an octet baryon is governed by two complex amplitudes; hence four quantities need to be measured to fully construct the amplitudes (up to an arbitrary phase per energy and angular bin). Discussions of complete experiments also generally assume perfect data (no experimental uncertainties); realistic uncertainties further complicate the task of amplitude extraction. Here, the available data are limited to the differential cross section and the target or hyperon recoil polarization P; data on the polarization transfer do not exist. The authors of Ref. [16] overcame this difficulty by using start values for the partial wave amplitudes determined in [17] and/or from an energy-dependent fit and by freezing or releasing sets of amplitudes. The resulting amplitudes were fitted with a unitary multichannel parameterization [11].

The JPAC group presented a coupled-channel fit to the $\bar{K}N$ partial waves derived by the Kent group [13]. The JPAC approach was based on the K-matrix formalism. Special attention was paid to the analytical properties of the amplitudes determined by the square-root unitary branch points and the continuation to the complex angular momentum plane. The fit described the Kent partial waves reasonably well. However, when observables were calculated from their partial-wave amplitudes, significant discrepancies became apparent. The results were therefore not included in the RPP.

The ANL-Osaka group derived the energy-dependent amplitudes in fits to a large subset of the data collected in Ref. [16] and further data sets described in Ref. [18]. Their fits were based on a phenomenological SU(3) Lagrangian [18]. The two ANL-Osaka models agree on the leading contributions but differ significantly in cases with weaker candidates [12].

Table 82.1: The status of the Λ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table. Decay channels other than $N\overline{K}$ and $\Sigma\pi$ are only given for *** and **** resonances.

			Status as seen in —		
Particle	J^P	Overall status	$N\overline{K}$	$\Sigma\pi$	Other channels
$\Lambda(1116)$	$1/2^+$	****			$N\pi$ (weak decay)
$\Lambda(1380)$	$1/2^-$	**	**	**	
$\Lambda(1405)$	$1/2^-$	****	****	****	
$\Lambda(1520)$	$3/2^-$	****	****	****	$\Lambda\pi\pi$, $\Lambda\gamma$, $\Sigma\pi\pi$
$\Lambda(1600)$	$1/2^+$	****	***	****	$\Lambda\pi\pi$, $\Sigma(1385)\pi$
$\Lambda(1670)$	$1/2^-$	****	****	****	$\Lambda\eta$
$\Lambda(1690)$	$3/2^-$	****	****	***	$\Lambda\pi\pi$, $\Sigma(1385)\pi$
$\Lambda(1710)$	$1/2^+$	*	*	*	
$\Lambda(1800)$	$1/2^-$	***	***	**	$\Lambda\pi\pi$, $N\overline{K}^*$
$\Lambda(1810)$	$1/2^+$	***	**	**	$N\overline{K}^*$
$\Lambda(1820)$	$5/2^+$	****	****	****	$\Sigma(1385)\pi$
$\Lambda(1830)$	$5/2^-$	****	****	****	$\Sigma(1385)\pi$
$\Lambda(1890)$	$3/2^+$	****	****	**	$\Sigma(1385)\pi$, $N\overline{K}^*$
$\Lambda(2000)$	$1/2^-$	*	*	*	
$\Lambda(2050)$	$3/2^-$	*	*	*	
$\Lambda(2070)$	$3/2^+$	*	*	*	
$\Lambda(2080)$	$5/2^-$	*	*	*	
$\Lambda(2085)$	$7/2^+$	**	**	*	
$\Lambda(2100)$	$7/2^-$	****	****	**	$N\overline{K}^*$
$\Lambda(2110)$	$5/2^+$	***	**	**	$N\overline{K}^*$
$\Lambda(2325)$	$3/2^-$	*	*		
$\Lambda(2350)$	$9/2^+$	***	***	*	
$\Lambda(2585)$		*	*		

The Bonn-Gatchina (BnGa) group added further (old) data to those analyzed in Ref. [16]. The data set was fitted in a modified K-matrix approach and the resulting amplitudes were compared with those from Refs. [16,18]. New resonances were found, other states, mostly one and two-star states could not be confirmed; all resonances were tested for their statistical significance. Additional states with any set of quantum numbers were tested and were found to produce only small improvements in the fit [14]. In Ref. [19], properties of the full set of contributing hyperons were reported.

The star ratings of Λ and Σ resonances given in our earlier editions, and the new results from the Kent, ANL-Osaka and BnGa groups were used to update the star rating of the hyperon resonances. In [19], the overall star rating is directly estimated, for [11] we estimate the star rating from the branching-ratio uncertainties. In [12], two solutions are given but no uncertainties for branching ratios. The overall star ratings are based on the evidence for the resonances in the new analyses as well as their consistency including also the results of earlier analyses given in [20]. For further details see also [15].

We decided to remove the three so-called *bumps* $\Sigma(1480)$, $\Sigma(1560)$, $\Sigma(1670)$, and $\Sigma(1690)$ as well as $\Sigma(1620)$ from production experiments. The entries from $\Sigma(1770)1/2^+$ are now listed under $\Sigma(1660)1/2^+$ and $\Sigma(1880)1/2^+$, the entries from $\Sigma(1730)3/2^+$ and $\Sigma(1840)3/2^+$ are now combined to one $\Sigma(1780)3/2^+$. The one-star $\Sigma(2000)1/2^-$ is combined with a new one-star $\Sigma(2160)1/2^-$ to a single one-star $\Sigma(2110)1/2^-$. Apart from $\Lambda(1380)1/2^-$, four further new resonances were included in the Listings: $\Lambda(2070)3/2^+$, $\Lambda(2080)5/2^-$, $\Sigma(2010)3/2^-$, and $\Sigma(2230)3/2^+$, all with one star.

Table 82.2: The status of the Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table. Decay channels other than $N\overline{K}$, $\Lambda\pi$ and $\Sigma\pi$ are only given for *** and **** resonances.

82.3 Sign conventions for resonance couplings

In terms of the isospin-0 and isospin-1 elastic scattering amplitudes A_0 and A_1, the amplitude for $K^-p \to \overline{K}^0 n$ scattering is $\pm(A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)5/2^-(D_{15})$ amplitude at resonance points along the positive imaginary axis (points "up"), then any Σ at resonance will point "up" and any Λ at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\overline{K}N \to \Lambda\pi$ and $\overline{K}N \to \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [21] and is shown in Fig. 82.1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or − sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). Also other decay modes can be used to assign a hyperon to a SU(3) multiplet [22, 23]. Modern analyses determine properties of resonances at the pole position. In these analyses, the + or − sign is replaced by a phase. Background amplitudes can lead to significant phase shifts, and an additional phase shift due to rescattering is admitted in some analyses. In comparison to quark model predictions [19,24], three Λ spin doublets can be identified as being mainly SU(3) singlets: the well-known ($\Lambda(1405)1/2^-$, $\Lambda(1520)3/2^-$), the ($\Lambda(2080)5/2^-$, $\Lambda(2100)7/2^-$), and ($\Lambda(2070)3/2^+$, $\Lambda(2110)5/2^+$).

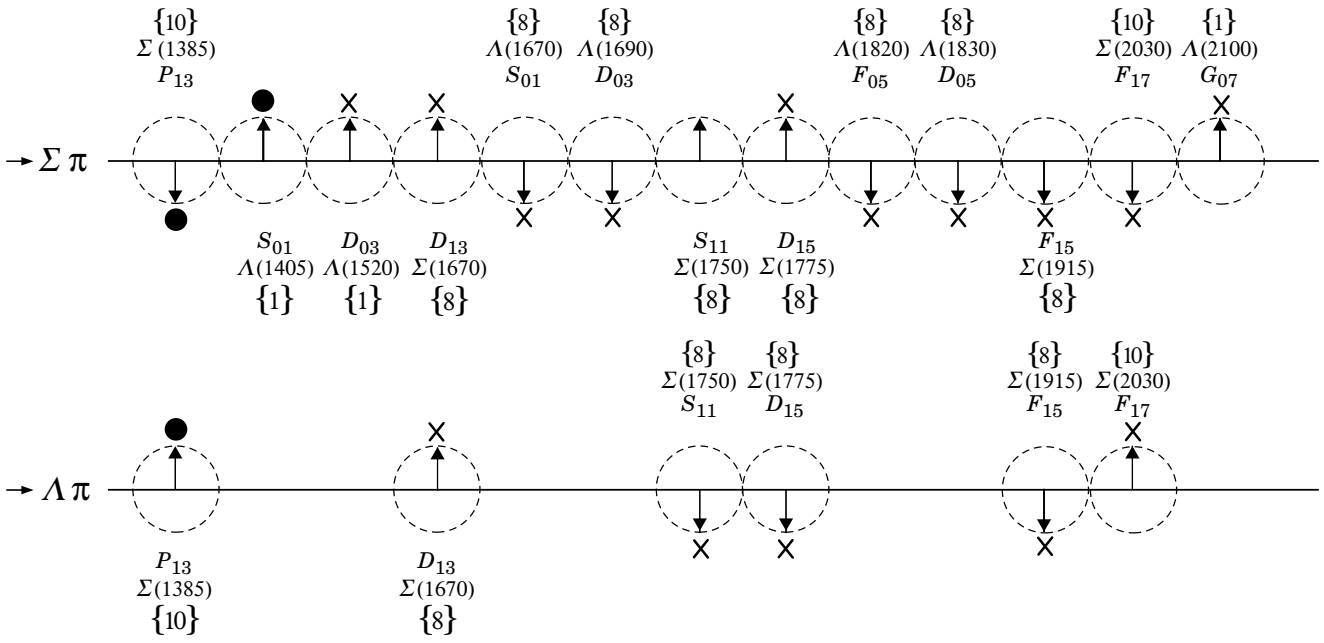

Figure 82.1: The signs of the imaginary parts of resonating amplitudes in the $\overline{K}N \to \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a •, are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an ×.

82.4 The $\Lambda(1405)$

In coupled-channels calculations based on the chiral SU(3) effective field theory, the strongly attractive forces between $N\overline{K}$ and $\Sigma\pi$ generate five poles, one SU(3) singlet pole, two Λ octet poles and two (or one) octet Σ poles (see Section 83). In quark models, these five states are $\Lambda(1405)$, $\Lambda(1670)$, $\Lambda(1800)$, $\Sigma(1620)$,

and $\Sigma(1750)$. The octet states are found 100 to 150 MeV above the corresponding nucleon resonances. In chiral SU(3) effective field theories, at least three of these states are seen in the 1300 to 1600 MeV mass range. The appearance of two Λ poles in this mass range, a narrow SU(3) octet at ∼1420 MeV and a wider SU(3) singlet at ∼1380 MeV, was unexpected. This approach has been pursued by a number of groups; for a summary of the results see our Review 83, "Pole Structure of the $\Lambda(1405)$ Region". In the Listings, we have introduced the $\Lambda(1380)$ as a new candidate resonance (with two stars), named in accordance with its approximate pole position. The second SU(3) octet Λ state is the well-known $\Lambda(1670)$. The masses of the two associated Σ states are uncertain so far, and no new entries are introduced in the Listings.

In traditional approaches only one resonance was seen in this mass region, the narrow state at 1405 MeV. It was reported to be the SU(3) singlet state a long time ago in Ref. [25], in agreement with the quark-model expectations but in contrast to the findings based on coupled-channels calculations within chiral SU(3) effective field theories. In the Listings, the $\Lambda(1405)$ has been retained with its traditional name. In quark models, this state is identified with the SU(3) singlet state, the two Λ octet states with $\Lambda(1670)$ and $\Lambda(1800)$, and the two Σ states with $\Sigma(1620)$ and $\Sigma(1750)$.

82.5 Uncertainties on masses and widths

The uncertainties quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change beyond these uncertainties when a different parametrization of the waves is used. Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted uncertainties. In the Listings, we usually give a range reflecting the spread of the values rather than a particular value with error.

82.6 Production experiments

Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. The $\Sigma(1385)$ and $\Lambda(1405)$ lie below the $\overline{K}N$ threshold and nearly everything about $\Sigma(1385)$ is learned from production experiments. Our knowledge on $\Lambda(1405)$ benefits greatly from photoproduction of the three $\Sigma\pi$ charge states [1, 2] and from the precise measurement of the energy shift and width of the kaonic hydrogen atom [26].

Production and formation experiments agree quite well in the case of $\Lambda(1520)$ and results have been combined. Above this mass, no new results on peak hunting have been reported for about 40 years. For these early results, we refer the reader to our earlier editions. In photoproduction with energetic photons [27, 28] or at LHCb [29], hyperons are produced abundantly. So far, no attempt has been made to extract hyperon properties from these data. New data on hyperon spectroscopy can be expected from J-PARC [30], JLAB [31], and the forthcoming PANDA experiment [32].

83. Pole Structure of the $\Lambda(1405)$ Region

Revised June 2021 by T. Hyodo (Tokyo Metropolitan U.) and U.-G. Meißner (Bonn U.; Jülich).

The $\Lambda(1405)$ resonance emerges in the meson-baryon scattering amplitude with the strangeness $S = -1$ and isospin $I = 0$. It is the archetype of what is called a dynamically generated resonance, as pioneered by Dalitz and Tuan [1]. The most powerful and systematic approach for the low-energy regime of the strong interactions is chiral perturbation theory (ChPT), see e.g. Ref. [2]. A perturbative calculation is, however, not applicable to this sector because of the existence of the $\Lambda(1405)$ just below the $\bar{K}N$ threshold. In this case, ChPT has to be combined with a non-perturbative resummation technique, just as in the case of the nuclear forces. By solving the Lippmann-Schwinger equation with the interaction kernel determined by ChPT and using a particular regularization, in Ref. [3] a successful description of the low-energy K^-p scattering data as well as the mass distribution of the $\Lambda(1405)$ was achieved (for further developments, see Ref. [4–7] and references therein).

The study of the pole structure was initiated by Ref. [8], which finds two poles of the scattering amplitude in the complex energy plane between the $\bar{K}N$ and $\pi\Sigma$ thresholds. The spectrum in experiments exhibits one effective resonance shape, while the existence of two poles results in the reaction-dependent lineshape [9]. The origin of this two-pole structure is attributed to the two attractive channels of the leading order interaction in the SU(3) basis (singlet and octet) [9] and in the isospin basis ($\bar{K}N$ and $\pi\Sigma$) [10]. It is remarkable that the sign and the strength of the leading order interaction is determined by a low-energy theorem of chiral symmetry, i.e. the so-called Weinberg-Tomozawa term. The two-pole nature of the $\Lambda(1405)$ is qualitatively different from the case of the N(1440) resonance. Two poles of the N(1440) appear on different Riemann sheets of the complex energy plane separated by the $\pi\Delta$ branch point. These poles reflect a single state, with a nearby pole and a more distant shadow pole. In contrast, the two poles in the $\Lambda(1405)$ region on the same Riemann sheet (where $\pi\Sigma$ channels are unphysical and all other channels physical, correspondingly to the one, connected to the real axis beween the $\pi\Sigma$ and $\bar{K}N$ thresholds) are generated from two attractive forces mentioned above [9, 10].

Recently, various new experimental results on the $\Lambda(1405)$ have become available [4]. Among these, the most striking measurement is the precise determination of the energy shift and width of kaonic hydrogen by the SIDDHARTA collaboration [11,12], which provides a quantitative and stringent constraint on the K^-p amplitude at threshold through the improved Deser formula [13]. Systematic studies with error analyses based on the next-to-leading order ChPT interaction including the SIDDHARTA constraint have been performed by various groups [14–18] All these studies confirm that the new kaonic hydrogen data are compatible with the scattering data above threshold.

The results of the pole positions of $\Lambda(1405)$ in the various approaches are summarized in Table 83.1. We may regard the difference among the calculations as a systematic error, which stems from the various approximations of the Bethe-Salpeter equation, the fitting procedure, and also the inclusion of SU(3) breaking effects such as the choice of the various meson decay constants, and so on. A detailed comparison of the various approaches that enter the table is given in Ref. [19]. A recent analysis including also the $J^P = 1/2^+$ P-wave contribution (and also an explicit $\Sigma(1385)$ $3/2^+$ state) gives results consistent with the findings reported above, with the pole positions at $(1364 - i43)$ MeV and $(1430 - i15)$ MeV, respectively [20].

The main component for the $\Lambda(1405)$ is the pole 1, whose position converges within a relatively small region near the $\bar{K}N$ threshold. On the other hand, the position of the pole 2 shows a sizeable scatter. Detailed studies of the $\pi\Sigma$ spectrum in various reaction processes, together with the precise experimental lineshape (see e.g. the recent precise photoproduction data from the LEPS collaboration [21] and from the CLAS collaboration [22,23], electroproduction data from the CLAS collaboration [24], and proton-proton collision data from COSY [25] and the HADES collaboration [26]), will shed light on the position of the second pole. The $\pi\Sigma$ spectra from the CLAS data are analyzed in Ref. [27] and Ref. [18]. It was shown in Ref. [18] that several solutions, which agree with the scattering data, are ruled out if confronted with the recent CLAS data. The remaining solutions are collected as solution #2 and solution #4 in Table 83.1. The HADES data are analyzed in Ref. [28] and Ref [29]. Although the result of the pole found in Ref. [28] is not compatible with other results, the authors of Ref. [29] invoke the anomalous triangle singularity mechanism to argue that the invariant mass distribution of the $\pi\Sigma$ system is found at lower masses than in other reactions. It is thus desirable to perform more comprehensive analyses of $\pi\Sigma$ spectra together with the systematic error analysis of the scattering data.

Table 83.1: Comparison of the pole positions of $\Lambda(1405)$ in the complex energy plane from next-to-leading order chiral unitary coupled-channel approaches including the SIDDHARTA constraint. The lower two results also include the CLAS photoproduction data.

84. Pentaquarks

Revised September 2021 by M. Karliner (Tel Aviv U.) and T. Skwarnicki (Syracuse U.).

Experimental searches for pentaquark hadrons comprised of light flavors have a long and vivid history. No undisputed candidates had been found in 50 years. The first wave of claimed observations of pentaquark candidates containing a strange antiquark occurred in the early seventies, see e.g. a review in the 1976 edition of Particle Data Group listings for $Z_0(1780)$, $Z_0(1865)$ and $Z_1(1900)$ [1]. The last mention of these candidates can be found in the 1992 edition [2] with the perhaps prophetic comment "the results permit no definite conclusion - the same story for 20 years. [...] The skepticism about baryons not made of three quarks, and lack of any experimental activity in this area, make it likely that another 20 years will pass before the issue is decided." A decade later, a second wave of observations occurred, possibly motivated by specific theoretical predictions for their existence [3–5]. The evidence for pentaquarks was based on observations of peaks in the invariant mass distributions of their decay products. More data and subsequent more sensitive experiments did not confirm these claims [6]. In the last mention of the best known candidate from that period, $\Theta(1540)^+$, the 2006 Particle Data Group listing [7] included a statement: "The conclusion that pentaquarks in general, and that Θ^+, in particular, do not exist, appears compelling." which well reflected the prevailing mood in the particle physics community until a study of $\Lambda_b^0 \to J/\psi p K^-$ ($J/\psi \to \mu^+\mu^-$) decays by LHCb [8] (charge conjugate modes are implied). From an analysis of 3 fb^{-1} Run 1 data at 7 and 8 TeV at the LHC, the LHCb collaboration reported a significant $J/\psi p$ structure in $\Lambda_b^0 \to J/\psi p K^-$ decays [8]. The exotic character of this structure, with the minimal quark content of $uudc\bar{c}$, was demonstrated in a nearly model-independent way in Ref. [9], where it was shown that the $J/\psi p$ mass ($m_{J/\psi p}$) peak near 4450 MeV was too narrow to be accounted for by $\Lambda^* \to pK^-$ reflections (Λ^* denotes a generic Λ excitation), reinforcing the results from the earlier model-dependent six-dimensional amplitude analysis of invariant masses and decay angles describing the Λ_b^0 decay in the same data [8]. Even though not apparent from the $m_{J/\psi p}$ distribution, the amplitude analysis also required a second broad $J/\psi p$ state to obtain a good description of the data, which peaked at $4380 \pm 8 \pm 29$ MeV with a width of $205 \pm 18 \pm 86$ MeV and a fit fraction of $(8.4 \pm 0.7 \pm 4.2)\%$.

The LHCb 6 fb^{-1} Run 2 LHC data at 13 TeV, together with the improvements in the data selection for both runs, resulted in a nine-fold increase in the number of reconstructed $\Lambda_b^0 \to J/\psi p K^-$ decays (246,000 events) [10]. When fit with the same six-dimensional amplitude model, the enlarged data sample gives consistent results for the $P_c(4450)^+$ and $P_c(4380)^+$ parameters, corroborating the compatibility of the data samples. However, the two-state interpretation of the data is contradicted by the observation of new narrow $J/\psi p$ structures which are too faint to have been significant in the Run 1 data analysis. A second horizontal band is observed in the Dalitz plot (Fig. 84.1) near 4312 MeV in the $J/\psi p$ mass.

The 4450 MeV structure also appears to consist of two narrower peaks at 4440 and 4457 MeV. Performing a rigorous six-dimensional amplitude analysis of these faint $J/\psi p$ structures is challenging and has not been accomplished yet. Fortunately, the newly observed peaks are so narrow that it is not necessary to construct an amplitude model to prove that these states are not artifacts of interfering Λ^* resonances, as was previously demonstrated in Ref. [9]. Their masses and widths have been characterized by the LHCb (see Table 84.1) from one-dimensional fits to $J/\psi p$ mass distributions, with different levels of suppression of the Λ^* contributions, which peak at the lower pK^- masses (Fig. 84.1). Such analysis is not sensitive to any broad $J/\psi p$ contributions like $P_c(4380)^+$. The histograms analyzed by the LHCb are available in tabular form at https://www.hepdata.net/record/89271.

The fit chosen by the LHCb for the central mass and width values is displayed in Fig. 84.2. The $P_c(4312)^+$ state peaks right below the $\Sigma_c^+ \bar{D}^0$ threshold and has statistical significance over 7.6σ. The $P_c(4457)^+$ state peaks right below the $\Sigma_c^+ \bar{D}^{*0}$ threshold, while the $P_c(4440)^+$ state peaks about 20 MeV below it. The significance of the two-peak versus one-peak hypothesis for the

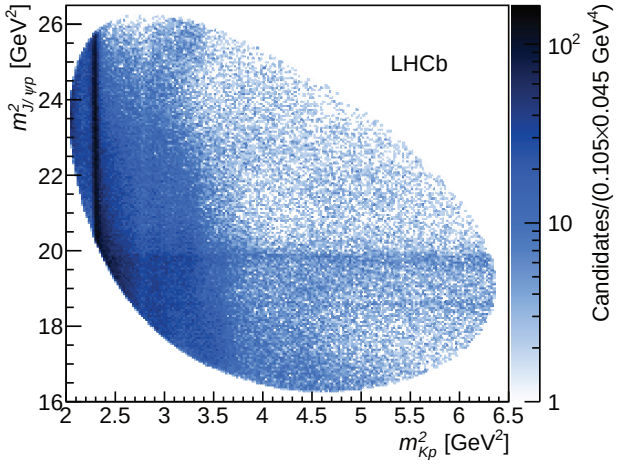

Figure 84.1: Dalitz plot distributions for $\Lambda_b^0 \to J/\psi p K^-$ decays as observed by LHCb.

4450 MeV structure is over 5.4σ, rendering the single peak interpretation of this region obsolete. The six-dimensional amplitude analysis reported in Ref. [8], which provided evidence for the $P_c(4380)^+$ state, is obsolete since it used the single $P_c(4450)^+$ state and it lacked the $P_c(4312)^+$ state. Furthermore, it used the helicity formalism in which the half-integer spin of the proton was not aligned properly between the different Λ_b decay chains [11, 12]. The newer one-dimensional analysis by LHCb [10] was not sensitive to wide P_c^+ states. The LHCb result from the six-dimensional amplitude analysis of the Cabibbo suppressed channel $\Lambda_b^0 \to J/\psi p \pi^-$ [13], which contains a statistically marginal evidence for the sum of the P_c^+ and the $Z_c(4200)^-$ contributions, took extensive input from Ref. [8] and, like the $P_c(4380)^+$ state, should be treated with caution until the both amplitude analyses are completed on the enlarged data sets with the modified helicity formalism.

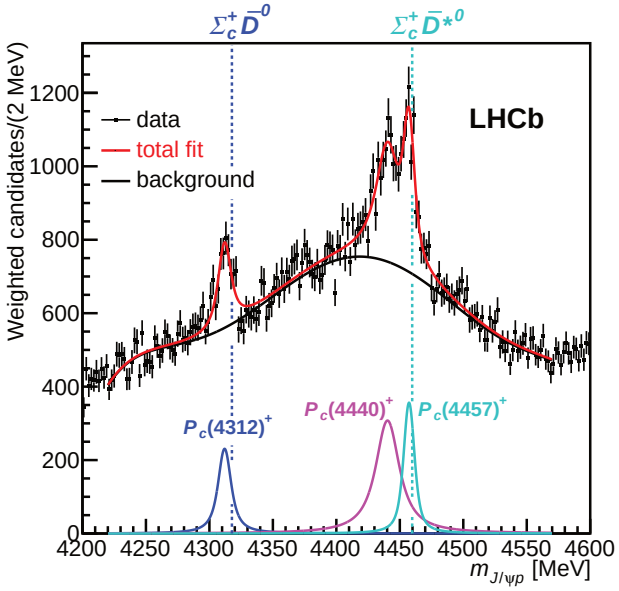

Figure 84.2: Fit to the $J/\psi p$ mass distribution, in which events were weighted to suppress $\Lambda^* \to pK^-$ backgrounds, of three Breit-Wigner functions and a sixth-order polynomial background. This fit was used to determine the central values of the masses and widths of the P_c^+ states reported by LHCb. The mass thresholds for the $\Sigma_c^+ \bar{D}^0$ and $\Sigma_c^+ \bar{D}^{*0}$ final states are superimposed.

While $\Sigma_c \bar{D}^{(*)}$ states had been predicted [14–17] before the first LHCb results [8], after these results became known, many theo-

Table 84.1: Summary of the narrow P_c^+ properties, interpreted as Breit-Wigner resonances. The central values are based on the fit displayed in Fig. 84.2.

State	M [MeV]	Γ [MeV] (95% CL)	$\mathcal{R}$ [%]
$P_c(4312)^+$	$4311.9 \pm 0.7^{+6.8}_{-0.6}$	$9.8 \pm 2.7^{+\ 3.7}_{-\ 4.5}$ (< 27)	$0.30 \pm 0.07^{+0.34}_{-0.09}$
$P_c(4440)^+$	$4440.3 \pm 1.3^{+4.1}_{-4.7}$	$20.6 \pm 4.9^{+\ 8.7}_{-10.1}$ (< 49)	$1.11 \pm 0.33^{+0.22}_{-0.10}$
$P_c(4457)^+$	$4457.3 \pm 0.6^{+4.1}_{-1.7}$	$6.4 \pm 2.0^{+\ 5.7}_{-\ 1.9}$ (< 20)	$0.53 \pm 0.16^{+0.15}_{-0.13}$

retical groups interpreted the $P_c(4450)^+$ and $P_c(4380)^+$ states in terms of diquarks and triquarks as building blocks of a compact pentaquark [18–24]. In a different strategy, a tentative attempt has been made to treat the full 5-body dynamics, leading to states below the lowest threshold for spontaneous dissociation [25]. In the first implementation of the former approach [18], the pentaquark mass splitting was generated mostly by the change of angular momentum between the sub-components (L) from zero to one, which would also make the heavier state narrower and of opposite parity. Explicit modeling of multiquark systems [26] questions if centrifugal barrier factor provides enough width suppression via spatial separation of c and $\bar{c}$ quarks at these masses, as the phase space for $J/\psi p$ decay is very large (more than 400 MeV). Also, the observed mass splitting was too small to be only due to the mechanism proposed in Ref. [18] and required fine-tuning of such models. A variation of this model, in which the heavy (cu) diquark couples with heavy $\bar{c}$ to form colored triquark attracting the light diquark (ud), has been re-implemented for the narrow P_c^+ states [27]. In this model, the $P_c(4440)^+$ and $P_c(4457)^+$ states are accommodated via spin-orbit interactions for the $L = 1$ states, while the $P_c(4312)^+$ is one of the $L = 0$ states. However, the mass prediction for the latter is off by (-72 ± 29) MeV [27]. This work was later extended to $SU(3)_F$ [28]. The width dilemma becomes more severe in view of the narrow widths of the newly observed states (Table 84.1), especially for the $L = 0$ $P_c(4312)^+$ state, and requires a different origin of potential barrier between c and $\bar{c}$ than angular momentum [27,29], which remains a subject of theoretical controversy. Measurement of spin-parity of $P_c(4312)^+$, $P_c(4440)^+$ and $P_c(4457)^+$ will be crucial for testing these and alternative theoretical ideas discussed in the following.

More effective width suppression mechanism is offered by a loosely bound charmed baryon-anticharmed meson molecular model, in which c and $\bar{c}$ can be separated by much larger distances, resulting in a smaller probability of them getting close enough to each other in order to make a J/ψ. Since molecular binding energy cannot be large, such molecules are in S-wave, so their masses must be near the sum of the baryon and meson masses and their spin and parity are inherited from their constituent hadrons [17]. The mass coincidence of the $P_c(4312)^+$ and of $P_c(4457)^+$ states, with the two related thresholds, $\Sigma_c^+ \bar{D}^0$ and $\Sigma_c^+ \bar{D}^{*0}$, provides very strong experimental evidence in favor of this interpretation. Given how close $P_c(4312)^+$ is to the $\Sigma_c^+ \bar{D}^0$ threshold, it might be a virtual rather than a bound state [30]. Since the spins of Σ_c^+ and of $\bar{D}^{*0}$ can be combined in two different ways, the narrow $P_c(4440)^+$ peak also finds natural explanation in this physical picture. It cannot be a virtual state since it is sufficiently below the $\Sigma_c^+ \bar{D}^{*0}$ threshold.

It is worth stressing that other baryon-meson combinations, $\Lambda_c^{(*)+} \bar{D}^{(*)0}$ and $\chi_{cJ} p$ are not expected to bind [14, 31]. Before the first pentaquark observation [8] heavy quark symmetry was used to show that, in addition to the three $\Sigma_c \bar{D}^{(*)0}$ states, one expects four $\Sigma_c^* \bar{D}^{(*)0}$ states, for a total of seven [32]. Indeed, additional states at, or below, the $\Sigma_c^{*+} \bar{D}$ and $\Sigma_c^{*+} \bar{D}^*$ thresholds, are expected [33–36]. Since Σ_c^{*+} width is likely around 15 MeV [37]. more than the width of either $P_c(4312)^+$ or $P_c(4457)^+$, it is important to keep in mind that a molecule is typically as broad as the constituents[1] [38–40]. For a review on hadronic molecules, see [41, 42].

It is useful to consider the $P_c(4312)^+$, $P_c(4440)^+$ and $P_c(4457)^+$ narrow pentaquarks together with several analogous exotic states with hidden charm and bottom in the meson sector. This provides additional significant motivation for the molecular model. At least five exotic mesons are close to thresholds of two heavy-light mesons: $X(3872)$ [43–46], $Z_b(10610)$ and $Z_b(10650)$ in the bottomonium sector [47–51] and $Z_c(3900)$ [52–56] and $Z_c(4020)$ [57–59] in the charmonium sector (see Table II in Ref. [60]; for reviews of experimental information see Ref. [61,62], as well as *Spectroscopy of Mesons Containing Two Heavy Quarks* and *Heavy Non-$q\bar{q}$ Mesons* in the current Review of Particle Properties. These states share several important features: a) their masses are near thresholds and their spin and parity correspond to S-wave combination of the two mesons; b) they are very narrow, despite very large phase space for decay into quarkonium + pion(s); c) the branching fractions for "fall apart" mode into two mesons are much larger than branching fractions for decay into quarkonium and pion(s). So far, there is no experimental evidence for states at two pseudoscalar thresholds ($D\bar{D}$ and $B\bar{B}$), implying that pseudoscalar exchange is essential for binding in meson-meson systems.

The above provide a strong hint that these states are deuteron-like loosely bound states of two heavy mesons [63–71]. It is then natural to conjecture that similar bound states might exist of two heavy baryons [72, 73], or a meson and a baryon or a baryon and an antibaryon, leading to a rather accurate prediction of the $P_c(4457)^+$ mass as $3/2^-$ $\Sigma_c \bar{D}^*$ molecule (the mass threshold is 4460 MeV for $\Sigma_c^+ D^{*0}$ and 4464 MeV for $\Sigma_c^{++} D^{*-}$) [17, 60], following similar predictions obtained in a wider framework of doubly heavy baryon-meson hadronic molecules, which might include mixtures of various two-hadron states [14–16, 31]. However, single pion exchange is not possible in $\Sigma_c^+ \bar{D}^0$ system, thus the existence of $P_c(4312)^+$ points to importance of vector or two-pion exchanges in baryon-meson molecules. Two-pion exchange in $D\bar{D}$ system is highly suppressed, because the intermediate state is $D^* \bar{D}^*$, which is 282 MeV heavier than $D\bar{D}$. On the other hand, there is little suppression in the $\Sigma_c \bar{D}$ system, because the dominant intermediate state is $\Lambda_c \bar{D}^*$ which is just 25 MeV lighter than $\Sigma_c \bar{D}$ [74]. In a generic hadronic molecule it is essential that the two hadrons are heavy, in order to minimize the repulsive kinetic energy [72,73,75].

Following the initial LHCb discovery [8], several groups carried out a detailed analysis of the P_c^+ states as hadronic molecules [76–85] followed by further analyses [35,86–110] after the updated LHCb results [10]. Partial widths of all the allowed decay channels for the P_c states have been estimated within a specific model in the molecular picture [111]. The most striking result is that $P_c(4312)$ decays are totally dominated by the $\bar{D}^* \Lambda_c$ channel. This channel is also expected to be very prominent in decays of $P_c(4440)$ and $P_c(4457)$. A recent theoretical analysis reaches an opposite conclusion, on the basis of the data available so far, expecting a rather small signal in the $\bar{D}^{(*)} \Lambda_c$ channels [112]. Obviously, experimental determination of the branching fraction of these channels is of high priority.

The P_c states have also been-interpreted as so called hadrocharmonium [113], a bound state of relatively compact charmonium states with light hadronic matter. It was proposed that $P_c(4440)^+$ and $P_c(4457)^+$ are spin-split $\psi(2S)p$ bound states with $J^P = \frac{1}{2}^-$ and $\frac{3}{2}^-$, while $P_c(4312)^+$ is a $\chi_{c0} p$ bound state with $J^P = \frac{1}{2}^+$ [114]. While very interesting from the theoretical point of view, it is not at all clear why the binding energies between charmonia and the nucleon should conspire to produce states so close to the $\Sigma_c \bar{D}$ and $\Sigma_c \bar{D}^*$ thresholds. Moreover, the predicted widths of $P_c(4440)^+$ and $P_c(4457)^+$ are too big by a factor $\sim$ 2-3. One should also keep in mind that the molecular and hadrocharmonium pictures provide opposite predictions for the parity

[1] This feature gets changed if systems are more deeply bound.

of $P_c(4312)^+$. In principle LHCb can check the spin and parity through partial wave analysis, but at present it is not known if systematic uncertainties can be sufficiently reduced to make such an analysis conclusive.

Shortly after the initial experimental discovery it was conjectured that the $P_c(4450)^+$ reflects the presence of a triangle singularity near the $\chi_{c1}p$ threshold [115–118]. These explanations are no longer viable, since the $P_c(4440)^+$ mass is not at any threshold and the $P_c(4312)^+$ and $P_c(4457)^+$ peak slightly below the $\Sigma_c^+\bar{D}^0$ and $\Sigma_c^+\bar{D}^{*0}$ thresholds. The $P_c(4457)^+$ mass is exactly at $\Lambda_c^{*+}\bar{D}^0$ threshold, but LHCb has demonstrated that the observed peaking is narrower in the data than expected from the triangle-diagram when a realistic width of the excited D_s^- state exchanged in the triangle is used (Supplemental Material in Ref. [10]).

More extensive pre-2019 reviews of some of the theoretical issues can be found in Refs. [119,120]. Two recent relevant reviews are Refs. [121,122].

So far the P_c^+ states have been observed by only one experiment in only one channel. It is essential to explore other possible experimental channels, such as $P_c \to \Lambda_c\bar{D}^{(*)}$, $\eta_c p$ [112]. These channels are however much more experimentally challenging than $P_c \to J/\psi p$. Proposals have also been made to search for heavy pentaquarks in photo-production [123–130]. Ref. [131] discusses photoproduction within the string-junction physical picture of the pentaquarks. Photoproduction is also related to recent work on $J/\psi(\eta_c)N$ scattering on the lattice [132] and on computation of $J/\psi(\eta_c)N$ and $\Upsilon(\eta_b)N$ cross sections [133]. In addition, pentaquark production has been discussed in the context of antiproton-deuterium collisions [134], of heavy ion collisions at LHC [135], in pA collisions [136] and in pion-induced processes [137–139]. The GlueX Collaboration reported negative search results for the P_c^+ states in photo-production at JLAB [140]. Within the large experimental errors and considerable theoretical model dependence these results do not contradict the molecular interpretations of the narrow P_c^+ states, especially in view of the P_c decay being likely dominated by $\Lambda_c\bar{D}^{(*)}$ modes [111,141]. It has been suggested to determine the pentaquark photo-couplings and branching ratios by measuring the polarization transfer between the incident photon and the outgoing proton in the exclusive photo-production of J/ψ near threshold [142].

As noted in e.g. [17], bottom analogues of the P_c^+ might well exist, but experimental search for such states involves very significant challenges. It is therefore hardly surprising that they have not been observed so far. A detailed discussion is beyond the scope of the current review.

Recently, the LHCb collaboration has obtained a 3.1σ evidence for a $P_c^+ \to J/\psi p$ state in the four-dimensional amplitude analysis of about 800 $B_s^0 \to J/\psi p\bar{p}$ ($J/\psi \to \mu^+\mu^-$) decays [143]. The mass of the state, $4337^{+7}_{-4} \pm 2$ MeV, is not compatible with the the $P_c(4312)^+$ state at 3.1 standard deviations. The width is relatively small, $29^{+26}_{-12} \pm 14$ MeV. The present data do not provide sufficient discrimination between various J^P assignments. Its mass is about 19 MeV higher than the $\Sigma_c^+\bar{D}^0$ threshold and about 16 MeV lower than the $\chi_{c0}p$ threshold. At present, no specific explanation for this structure has been proposed, but some intriguing ideas have been raised in Ref. [144]. Since the statistical significance of this evidence is marginal, more data are required before this state is considered experimentally established.

Similarly inconclusive 3.1σ evidence for a $P_{cs}^0 \to J/\psi\Lambda$ structure was observed by the LHCb collaboration in the six-dimensional amplitude analysis of about 1750 $\Xi_b^- \to J/\psi\Lambda K^-$ ($J/\psi \to \mu^+\mu^-$, $\Lambda \to p\pi^-$ decays [12]. The strange counterparts of P_c^+ states have been predicted in both molecular and compact pentaquark models [15,98,100,145–147]. When interpreted as a single peak, its mass, $4458.8 \pm 2.9^{+4.7}_{-1.1}$ MeV, is 15 MeV above the $\Xi_c^{0\prime}\bar{D}^0$ threshold and 18 MeV below the $\Xi_c^0\bar{D}^{*0}$ threshold. Its width, $17.3 \pm 6.5^{+8.0}_{-5.7}$ MeV, is relatively narrow, thus plausibly could be interpreted as a loosely bound $\Xi_c^0\bar{D}^{*0}$ state. However, in the latter model two states are expected with J^P equal to $1/2^-$ and $3/2^-$. In fact, the LHCb data are consistent with such hypothesis, under which 4454.9 ± 2.7 MeV ($\Gamma = 7.5 \pm 9.7$ MeV) and 4467.8 ± 3.7 MeV ($\Gamma = 5.2 \pm 5.3$ MeV) mass (width) estimates are obtained (statistical errors only). It is worth noting, that the $SU(3)$ flavor structure of $\Xi_c^0\bar{D}^{*0}$ states is different from that of $\Sigma_c^+\bar{D}^{*0}$ states, since Ξ_c^0 belongs to the charmed baryon triplet, unlike Σ_c^+, which together with $\Xi_c^{0\prime}$, belong to the charmed baryon sextet. More data are required to experimentally establish this structure, clarify its composition, and determine the related quantum numbers.

If $P_{cs}(4459)^0$ indeed is a $\Xi_c^0\bar{D}^{*0}$ molecule, there likely exists another state, corresponding to $\Xi_c'\bar{D}^*$ [15,98,100,145–147], with a mass shifted upwards by approximately $\Xi_c' - \Xi_c$ mass difference [148], i.e. about 108 MeV [37]. Experimental determination whether yet additional $\Xi_c^{(*,\prime)}\bar{D}^{(*)0}$ states actually exist will provide a useful testing ground for the various theoretical approaches which have been used to predict them.

In hidden-charm exotics discussed above, the charmed and the anticharmed quarks can form a charmonium and thereby decouple from the light quarks. The molecular model provides an efficient mechanism to suppress such decays, thus making these states narrow. This type of exotic states, should not be confused with exotic hadrons containing two heavy quarks, rather than a heavy quark and a heavy antiquark. Such a decoupling is impossible in exotics which contain two heavy quarks. This has far-reaching consequences.

The first exotic hadron containing two heavy quarks has recently been reported by LHCb [149,150] and deserves a separate review. Here we briefly discuss only the essential distinction vs. hidden-charm pentaquarks. The reported T_{cc}^+ state has quark content $cc\bar{u}\bar{d}$, $I = 0$ and likely $J^P = 1^+$, and mass about 300 keV below the D^0D^{*+} threshold. Its width is a fraction of an MeV. The phase space available for decay is tiny due to absence of the decoupling mechanism. Therefore the narrow width of T_{cc}^+ is natural in both the compact tetraquark model and in those molecular models which predict the mass very close to the D^0D^{*+} threshold. On the other hand, for sufficiently heavy quarks, e.g. $bb\bar{u}\bar{d}$, such open heavy-flavor exotics are genuine compact tetraquarks which are *stable* under strong interactions; see discussion and references in Refs. [149,150].

It is quite possible that compact tetraquark states exist also for states with hidden-flavor, but such states are expected to be broader because of the decoupling mechanism. In fact, there is plenty of evidence for them in form of mass structures in $J/\psi\phi$ [151–156], $J/\psi J/\psi$ [157], $Z_c(4430)^+ \to \psi(2S)\pi^+$ [158–160] and others, although alternative explanations of these structures have been also proposed. Analogous configurations may also exist for pentaquarks, but there is no firm evidence for them yet.

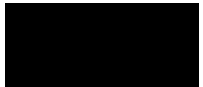
Hypothetical Particles and Concepts



85. Extra Dimensions

Revised August 2021 by Y. Gershtein (Rutgers U.) and A. Pomarol (U. Autònoma de Barcelona; IFAE).

85.1 Introduction

Proposals for a spacetime with more than three spatial dimensions date back to the 1920s, mainly through the work of Kaluza and Klein, in an attempt to unify the forces of nature [1]. Although their initial idea failed, the formalism that they and others developed is still useful nowadays. Around 1980, string theory proposed again to enlarge the number of space dimensions, this time as a requirement for describing a consistent theory of quantum gravity. The extra dimensions were supposed to be compactified at a scale close to the Planck scale, and thus not testable experimentally in the near future.

A different approach was given by Arkani-Hamed, Dimopoulos, and Dvali (ADD) in their seminal paper in 1998 [2], where they showed that the weakness of gravity could be explained by postulating two or more flat extra dimensions in which only gravity could propagate. The size of these extra dimensions should range between roughly a millimeter and ∼1/TeV, leading to possible observable consequences in current and future experiments. A year later, Randall and Sundrum (RS) [3] found a new possibility using a warped geometry, postulating a five-dimensional Anti-de Sitter (AdS) spacetime with a compactification scale of order 1/TeV. The origin of the smallness of the electroweak scale versus the Planck scale was explained by the gravitational redshift factor present in the warped AdS metric. As in the ADD model, originally only gravity was assumed to propagate in the extra dimensions, although it was soon clear that this was not necessary in warped extra dimensions and also the SM gauge fields [4, 5] and SM fermions [6, 7] could propagate in the five-dimensional spacetime.

The physics of warped extra-dimensional models has an alternative interpretation by means of the AdS/CFT correspondence [8–10]. Models with warped extra dimensions are related to four-dimensional strongly-interacting theories, allowing an understanding of the properties of five-dimensional fields as those of four-dimensional composite states [11]. This approach has opened new directions for tackling outstanding questions in particle physics, such as the flavor problem, grand unification, and the origin of electroweak symmetry breaking or supersymmetry breaking.

85.1.1 *Experimental Constraints*

Constraints on extra-dimensional models arise from astrophysical and cosmological considerations, tabletop experiments exploring gravity at sub-mm distances, and collider experiments. Collider limits on extra-dimensional models are dominated by LHC results, which can be found on the public WWW pages of ATLAS [12] and CMS [13]. This review includes the most recent limits, most of which are published results based on 140 fb^{-1}LHC data collected in 2015-18 at a center-of-mass energy of 13 TeV and legacy results from 20 $\text{fb}^{-1}$of 8 TeV data collected in Run 1. For most of the models, Run 2 results surpass the sensitivity of Run 1.

85.1.2 *Kaluza-Klein Theories*

Field theories with compact extra dimensions can be written as theories in ordinary four dimensions (4D) by performing a Kaluza-Klein (KK) reduction. As an illustration, consider a simple example, namely a field theory of a complex scalar in flat five-dimensional (5D) spacetime. The action will be given by [1]

$$S_5 = -\int d^4x\, dy\, M_5 \left[|\partial_\mu \phi|^2 + |\partial_y \phi|^2 + \lambda_5 |\phi|^4\right] , \qquad (85.1)$$

where y refers to the extra (fifth) dimension. A universal scale M_5 has been extracted in front of the action in order to keep the 5D field with the same mass-dimension as in 4D. This theory is perturbative for energies $E \lesssim \ell_5 M_5/\lambda_5$ where $\ell_5 = 24\pi^3$ [14].

[1] Our convention for the metric is $\eta_{MN} = \text{Diag}(-1, 1, 1, 1, 1)$.

Let us now consider that the fifth dimension is compact with the topology of a circle S^1 of radius R, which corresponds to the identification of y with $y + 2\pi R$. In such a case, the 5D complex scalar field can be expanded in a Fourier series:

$$\phi(x, y) = \frac{1}{\sqrt{2\pi R M_5}} \sum_{n=-\infty}^{\infty} e^{iny/R} \phi^{(n)}(x) , \qquad (85.2)$$

that, inserted in Eq. (85.1) and integrating over y, gives

$$S_5 = S_4^{(0)} + S_4^{(n)} , \qquad (85.3)$$

where

$$S_4^{(0)} = -\int d^4x \left[|\partial_\mu \phi^{(0)}|^2 + \lambda_4 |\phi^{(0)}|^4\right] , \qquad (85.4)$$

and,

$$S_4^{(n)} = -\int d^4x \sum_{n\neq 0} \left[|\partial_\mu \phi^{(n)}|^2 + \left(\frac{n}{R}\right)^2 |\phi^{(n)}|^2\right] + \text{quartic interactions} . \qquad (85.5)$$

The $n = 0$ mode self-coupling is given by

$$\lambda_4 = \frac{\lambda_5}{2\pi R M_5} . \qquad (85.6)$$

The above action corresponds to a 4D theory with a massless scalar $\phi^{(0)}$, referred to as the zero mode, and an infinite tower of massive modes $\phi^{(n)}$ with $n > 0$, known as KK modes. The KK reduction thus allows a treatment of 5D theories as 4D field theories with an infinite number of fields. At energies smaller than $1/R$, the KK modes can be neglected, leaving the zero-mode action of Eq. (85.4). The strength of the interaction of the zero-mode, given by Eq. (85.6), decreases as R increases. Thus, for a large extra dimension $R \gg 1/M_5$, the massless scalar is very weakly coupled.

85.2 Large Extra Dimensions for Gravity

85.2.1 *The ADD Scenario*

The ADD scenario [2, 15] (for a review see, for example, [16]) assumes a $D = 4 + \delta$ dimensional spacetime, with δ compactified spatial dimensions. The apparent weakness of gravity arises since it propagates in the higher-dimensional space. The SM is assumed to be localized in a 4D subspace, a 3-brane, as can be found in certain string theory constructions [17, 18]. Gravity is described by the Einstein-Hilbert action in $D = 4 + \delta$ spacetime dimensions

$$S_D = -\frac{\bar{M}_D^{2+\delta}}{2} \int d^4x d^\delta y \sqrt{-g}\, \mathcal{R} + \int d^4x \sqrt{-g_{\text{ind}}}\, \mathcal{L}_{\text{SM}} , \qquad (85.7)$$

where x labels the ordinary four coordinates, y the δ extra coordinates, g refers to the determinant of the D-dimensional metric whose Ricci scalar is defined by $\mathcal{R}$, and $\bar{M}_D$ is called the reduced Planck scale of the D-dimensional theory. In the second term of Eq. (85.7), which gives the gravitational interactions of SM fields, the D-dimensional metric reduces to the induced metric on the 3-brane where the SM fields propagate. The extra dimensions are assumed to be flat and compactified in a volume V_δ. As an example, consider a toroidal compactification of equal radii R and volume $V_\delta = (2\pi R)^\delta$. After a KK reduction, one finds that the fields that couple to the SM are the spin-2 gravitational field $G_{\mu\nu}(x, y)$ and a tower of spin-0 KK graviscalars [19]. The graviscalars, however, only couple to SM fields through the trace of the energy-momentum tensor, resulting in weaker couplings to the SM fields. The Fourier expansion of the spin-2 field is given by

$$G_{\mu\nu}(x, y) = G_{\mu\nu}^{(0)}(x) + \frac{1}{\sqrt{V_\delta}} \sum_{\vec{n}\neq 0} e^{i\vec{n}\cdot\vec{y}/R} G_{\mu\nu}^{(\vec{n})}(x) , \qquad (85.8)$$

where $\vec{y} = (y_1, y_2, ..., y_\delta)$ are the extra-dimensional coordinates and $\vec{n} = (n_1, n_2, ..., n_\delta)$. Eq. (85.8) contains a massless state,

the 4D graviton $G^{(0)}_{\mu\nu}$, and its KK tower $G^{(\vec{n})}_{\mu\nu}$ with masses $m^2_{\vec{n}} = |\vec{n}|^2/R^2$. At energies below $1/R$ the action is that of the zero mode

$$S^{(0)}_4 = -\frac{\bar{M}_D^{2+\delta}}{2}\int d^4x\, V_\delta \sqrt{-g^{(0)}}\,\mathcal{R}^{(0)} + \int d^4x \sqrt{-g^{(0)}_{\rm ind}}\,\mathcal{L}_{\rm SM}\,, \tag{85.9}$$

where we can identify the 4D reduced Planck mass, $M_P \equiv 1/\sqrt{8\pi G_N} \simeq 2.4\times 10^{18}$ GeV, as a function of the D-dimensional parameters:

$$M_P^2 = V^\delta \bar{M}_D^{2+\delta} \equiv R^\delta M_D^{2+\delta}\,. \tag{85.10}$$

Fixing M_D at around the electroweak scale $M_D \sim$ TeV to avoid introducing a new mass scale in the model, Eq. (85.10) gives a prediction for R:

$$\delta = 1, 2, ..., 6 \;\rightarrow\; R \sim 10^9 \text{ km}\,, 0.5 \text{ mm}\,, ...\,, 0.1 \text{ MeV}^{-1}\,. \tag{85.11}$$

The option $\delta = 1$ is clearly ruled out, as it leads to modifications of Newton's law at solar system distances. However this is not the case for $\delta \geq 2$, and possible observable consequences can be sought in present and future experiments.

Consistency of the model requires a stabilization mechanism for the radii of the extra dimensions, to the values shown in Eq. (85.11). The fact that we need $R \gg 1/M_D$ leads to a new hierarchy problem, the solution of which might require imposing supersymmetry in the extra-dimensional bulk (for the case of two extra dimensions see for example [20]).

85.2.2 *Tests of the Gravitational Force Law at Sub-mm Distances*

The KK modes of the graviton give rise to deviations from Newton's law of gravitation for distances $\lesssim R$. Such deviations are usually parameterized by a modified Newtonian potential of the form

$$V(r) = -G_N \frac{m_1 m_2}{r}\left[1 + \alpha\, e^{-r/\lambda}\right]\,. \tag{85.12}$$

For a 2-torus compactification, $\alpha = 16/3$ and $\lambda = R$. Searches for deviations from Newton's law of gravitation have been performed in several experiments [21–24]. From Ref. [23] we have the constraint $R < 30\mu$m at 95% CL for $\delta = 2$, corresponding to $M_D > 4.0$ TeV. We see then that bounds from Newton's law deviations are already pushing the scale M_D beyond the TeV for two extra dimensions.

85.2.3 *Astrophysical and Cosmological Constraints*

The light KK gravitons could be copiously produced in stars, carrying away energy. Ensuring that the graviton luminosity is low enough to preserve the agreement of stellar models with observations provides powerful bounds on the scale M_D. The most stringent bound arises from supernova SN1987A, giving $M_D > 27$ (2.4) TeV for $\delta = 2$ (3) [25]. After a supernova explosion, most of the KK gravitons stay gravitationally trapped in the remnant neutron star. The requirement that neutron stars are not excessively heated by KK decays into photons leads to $M_D > 1700$ (76) TeV for $\delta = 2$ (3) [26].

Cosmological constraints are also quite stringent [27]. To avoid overclosure of the Universe by relic gravitons one needs $M_D > 7$ TeV for $\delta = 2$. Relic KK gravitons decaying into photons contribute to the cosmic diffuse gamma radiation, from which one can derive the bound $M_D > 100$ TeV for $\delta = 2$.

We must mention however that bounds coming from the decays of KK gravitons into photons can be reduced if we assume that KK gravitons decay mainly into other non-SM states. This could happen, for example, if there were other 3-branes with hidden sectors residing on them [15].

85.2.4 *Collider Signals*

85.2.4.1 *Graviton and Other Particle Production*

Although each KK graviton has a purely gravitational coupling, suppressed by $1/M_P$, inclusive processes in which one sums over the almost continuous spectrum of available gravitons have cross sections suppressed only by powers of M_D. Processes involving gravitons are therefore detectable in collider experiments if $M_D \sim$ TeV. A number of experimental searches for evidence of large extra dimensions have been performed at colliders, and interpreted in the context of the ADD model.

One signature arises from direct graviton emission. By making a derivative expansion of Einstein gravity, one can construct an effective theory, valid for energies much lower than M_D, and use it to make predictions for graviton-emission processes at colliders [19, 28, 29]. Gravitons produced in the final state would escape detection, giving rise to missing transverse energy ($\not{E}_T$). The results quoted below are 95% CL lower limits on M_D for a range of values of δ between 2 and 6, with more stringent limits corresponding to lower δ values.

At hadron colliders, experimentally sensitive channels include the jet $(j) + \not{E}_T$ and $\gamma + \not{E}_T$ final states. ATLAS (CMS) $j + \not{E}_T$ results with 139 (137) fb^{-1} of 13 TeV data provide limits of $M_D > 5.9 - 11.2$ TeV [30] ($M_D > 5.5 - 10.7$ TeV [31]). For these analyses, both experiments are assuming leading order (LO) cross sections. Since the effective theory is only valid for energies much less than M_D, the results are quoted for the full space, and include the information that suppressing the graviton cross section by a factor $M_D^4/\hat{s}^2$ for $\sqrt{\hat{s}} > M_D$, where $\sqrt{\hat{s}}$ is the parton-level center-of-mass energy of the hard collision, weakens the limits on M_D by a negligible amount for $\delta = 2$ ($\sim$3% for $\delta = 6$). Less stringent limits are obtained by CMS [32] from analysis of 36 fb^{-1}of 13 TeV data in the $\gamma + \not{E}_T$ final state ($M_D > 2.85-2.90$ TeV for $\delta = 3-6$). The analogous ATLAS search [33] uses full Run 2 statistics but does not quote ADD interpretation of the results.

In models in which the ADD scenario is embedded in a string theory at the TeV scale [18], we expect the string scale M_s to be smaller than M_D, and therefore expect production of string resonances at the LHC [34]. A result from CMS analyzing the dijet invariant mass distribution for 137 fb^{-1}of 13 TeV data excludes string resonances that decay predominantly to $q + g$ with masses below 7.9 TeV [35]. ATLAS dijet analysis [36] provides their results in the context of model-independent limits on the cross section times acceptance for generic resonances of a variety of possible widths, from which one can deduce similar lower mass limits ~ 8 TeV for string resonances decaying to $q + g$.

85.2.4.2 *Virtual graviton effects*

One can also search for virtual graviton effects, the calculation of which however depends on the ultraviolet cut-off of the theory and is therefore very model dependent. In the literature, several different formulations exist [19,29,37] for the dimension-eight operator for gravity exchange at tree level:

$$\mathcal{L}_8 = \pm\frac{4}{M_{TT}^4}\left(T_{\mu\nu}T^{\mu\nu} - \frac{1}{\delta+2}T^\mu_\mu T^\nu_\nu\right), \tag{85.13}$$

where $T_{\mu\nu}$ is the energy-momentum tensor and M_{TT} is related to M_D by some model-dependent coefficient [38]. The relations with the parametrization of Refs. [37] and [19] are, respectively, $M_{TT} = M_S$ and $M_{TT} = (2/\pi)^{1/4}\Lambda_T$. The experimental results below are given as 95% CL lower limits on M_{TT}, including in some cases the possibility of both constructive or destructive interference, depending on the sign chosen in Eq. (9).

The most stringent limits arise from LHC analyses of the dijet angular distribution. Using 35.9 fb^{-1}of 13 TeV data, CMS [39] obtains results that correspond to an approximate limit of $M_{TT} >$ 9.1 TeV.

The next most restrictive results come from the analyses of diphoton ($M_{TT} > 6.1$ TeV from ATLAS [40] and $M_{TT} > 7.0$ TeV from CMS [41]) and dilepton mass spectra ($M_{TT} > 6.5$ TeV from CMS [42]). The complete Run 2 (139 fb^{-1}) analysis of ATLAS di-lepton data [43] does not quote the limits on ADD.

At the one-loop level, gravitons can also generate dimension-six operators with coefficients that are also model dependent. Experimental bounds on these operators can also give stringent constraints on M_D [38].

85.2.4.3 *Black Hole Production*

The physics at energies $\sqrt{s} \sim M_D$ is sensitive to the details of the unknown quantum theory of gravity. Nevertheless, in the transplanckian regime, $\sqrt{s} \gg M_D$, one can rely on a semiclassical description of gravity to obtain predictions. An interesting feature of transplanckian physics is the creation of black holes [44,45] (for

a review see, for example, [46]). A black hole is expected to be formed in a collision in which the impact parameter is smaller than the Schwarzschild radius [47]:

$$R_S = \frac{1}{M_D}\left[\frac{2^\delta \pi^{(\delta-3)/2}}{\delta+2}\Gamma\left(\frac{\delta+3}{2}\right)\frac{M_{BH}}{M_D}\right]^{1/(\delta+1)}, \quad (85.14)$$

where M_{BH} is the mass of the black hole, which would roughly correspond to the total energy in the collision. The cross section for black hole production can be estimated to be of the same order as the geometric area $\sigma \sim \pi R_S^2$. For $M_D \sim$ TeV, this gives a production of $\sim 10^7$ black holes at the $\sqrt{s} = 14$ TeV LHC with an integrated luminosity of 30 fb^{-1} [44,45]. A black hole would provide a striking experimental signature since it is expected to thermally radiate with a Hawking temperature $T_H = (\delta+1)/(4\pi R_S)$, and therefore would evaporate democratically into all SM states. Nevertheless, given the present constraints on M_D, the LHC will not be able to reach energies much above M_D. This implies that predictions based on the semiclassical approximation could receive sizable modifications from model-dependent quantum-gravity effects.

The most stringent limits on microscopic black holes arise from LHC searches which observed no excesses above the SM background in high-multiplicity final states. The results are usually quoted as model-independent limits on the cross section for new physics in the final state and kinematic region analyzed. These results can then be used to provide constraints of models of low-scale gravity and weakly-coupled string theory. In addition, limits are sometimes quoted on particular implementations of models, which are used as benchmarks to illustrate the sensitivity.

A CMS analysis [48] of multi-object final states using 36 fb^{-1}of 13 TeV data, excludes semiclassical black holes below masses of up to 10.1 TeV for $M_D = 2$ TeV and $\delta = 6$. Analogous Run 2 ATLAS analysis [49], using 3.0 fb^{-1}of 13 TeV data, excludes black hole masses up to $9.0 - 9.7$ TeV, depending on M_D, for $\delta = 6$. Another ATLAS search [50] for an excess of events with multiple high transverse momentum objects, including charged leptons and jets, using 3.2 fb^{-1}of 13 TeV data, excludes semiclassical black holes below masses of ~ 8.7 TeV for $M_D = 2$ TeV and $\delta = 6$.

A complementary approach is to look for jet extinction at high transverse momenta, as we expect hard short distance scattering processes to be highly suppressed at energies above M_D [51]. The CMS analysis [52] of inclusive jet p_T spectrum in 10.7 fb^{-1}of 8 TeV data set a lower limit of 3.3 TeV on the extinction mass scale.

For black hole masses near M_D, the semi-classical approximation is not valid, and one could instead expect quantum black holes (QBH) that decay primarily into two-body final states [53]. LHC Run 2 results at 13 TeV provide lower limits on QBH masses of order $2.3 - 9.4$ TeV, depending on the details of the model. Searches that consider interpretations in terms of QBH limits include the CMS multi-object analysis (based on 2.3 fb^{-1} [54]), ATLAS dijet analysis (based on 139 fb^{-1} [36]), and different flavor di-lepton analyses at CMS ($e\mu$, 36 fb^{-1} at 13 TeV [55]) and ATLAS ($e\mu$, $e\tau$, $\mu\tau$, 36.1 fb^{-1} at 13 TeV [56]).

So [36] relies on 139 fb-1 and [54] relies on 2.3 fb-1.

In weakly-coupled string models the semiclassical description of gravity fails in the energy range between M_s and M_s/g_s^2 where stringy effects are important. In this regime one expects, instead of black holes, the formation of string balls, made of highly excited long strings, that could be copiously produced at the LHC for $M_s \sim$ TeV [57], and would evaporate thermally at the Hagedorn temperature giving rise to high-multiplicity events. The same analyses used to search for black holes can be interpreted in the context of string balls. For example, for the case of $\delta = 6$ with $M_s = M_D/1.26 = 3$ TeV, the ATLAS multiple high transverse momentum object analysis [49] excludes string balls with masses below 6.5 to 9.0 TeV for values of $0.2 < g_s < 0.8$. The CMS multi-object analysis [48] studies string ball production in two scenarios, both assuming $\delta = 6$. For the constant $g_s = 0.2$ and $1 < M_s < 3.5$ TeV the string ball masses below 7.2 to 9.4 TeV are excluded, while at constant $M_s = 3.6$ TeV and $0.2 < g_s < 0.4$ masses below 7.2 to 8.1 TeV are excluded.

85.3 TeV-Scale Extra Dimensions

85.3.1 *Warped Extra Dimensions*

The RS model [3] is the most attractive setup of warped extra dimensions at the TeV scale, since it provides an alternative solution to the hierarchy problem. The RS model is based on a 5D theory with the extra dimension compactified in an orbifold, S^1/Z_2, a circle S^1 with the extra identification of y with $-y$. This corresponds to the segment $y \in [0, \pi R]$, a manifold with boundaries at $y = 0$ and $y = \pi R$. Let us now assume that this 5D theory has a cosmological constant in the bulk Λ, and on the two boundaries Λ_0 and $\Lambda_{\pi R}$:

$$S_5 = -\int d^4x\, dy \Big\{ \sqrt{-g}\Big[\frac{1}{2}M_5^3\mathcal{R} + \Lambda\Big] + \sqrt{-g_0}\,\delta(y)\Lambda_0 + \sqrt{-g_{\pi R}}\,\delta(y-\pi R)\Lambda_{\pi R}\Big\}, \quad (85.15)$$

where g_0 and $g_{\pi R}$ are the values of the determinant of the induced metric on the two respective boundaries. Einstein's equations can be solved, giving in this case the metric

$$ds^2 = a(y)^2 dx^\mu dx^\nu \eta_{\mu\nu} + dy^2\,, \quad a(y) = e^{-ky}\,, \quad (85.16)$$

where $k = \sqrt{-\Lambda/6M_5^3}$. Consistency of the solution requires $\Lambda_0 = -\Lambda_{\pi R} = -\Lambda/k$. The metric in Eq. (85.16) corresponds to a 5D AdS space. The factor $a(y)$ is called the "warp" factor and determines how 4D scales change as a function of the position in the extra dimension. In particular, this implies that energy scales for 4D fields localized at the boundary at $y = \pi R$ are redshifted by a factor $e^{-k\pi R}$ with respect to those localized at $y = 0$. For this reason, the boundaries at $y = 0$ and $y = \pi R$ are usually referred to as the ultraviolet (UV) and infrared (IR) boundaries, respectively.

As in the ADD case, we can perform a KK reduction and obtain the low-energy effective theory of the 4D massless graviton. In this case we obtain

$$M_P^2 = \int_0^{\pi R} dy\, e^{-2ky} M_5^3 = \frac{M_5^3}{2k}\left(1 - e^{-2k\pi R}\right). \quad (85.17)$$

Taking $M_5 \sim k \sim M_P$, we can generate an IR-boundary scale of order $ke^{-k\pi R} \sim$ TeV for an extra dimension of radius $R \simeq 11/k$. Mechanisms to stabilize R to this value have been proposed [58,59] that, contrary to the ADD case, do not require introducing any new small or large parameter. Therefore a natural solution to the hierarchy problem can be achieved in this framework if the Higgs field, whose vacuum expectation value (VEV) is responsible for electroweak symmetry breaking, is localized at the IR-boundary where the effective mass scales are of order TeV. The radion field is generically heavy in models with a stabilized R. Nevertheless, it has been recently discussed that under some conditions a naturally light radion can arise [60–63]. In these cases the radion is identified with the dilaton, the Nambu-Goldstone boson associated to the spontaneous breaking of scale invariance, and its mass can be naturally below $ke^{-k\pi R} \sim$ TeV. Collider bounds on the radion mass and couplings can be found in [64–66].

In the RS model [3], all the SM fields were assumed to be localized on the IR-boundary. Nevertheless, for the hierarchy problem, only the Higgs field has to be localized there. SM gauge bosons and fermions can propagate in the 5D bulk [4–7] (for a review see, for example, [67, 68]). By performing a KK reduction from the 5D action of a gauge boson, we find [4, 5]

$$\frac{1}{g_4^2} = \int_0^{\pi R} dy\, \frac{1}{g_5^2} = \frac{\pi R}{g_5^2}\,, \quad (85.18)$$

where g_D ($D = 4, 5$) is the gauge coupling in D-dimensions. Therefore the 4D gauge couplings can be of order one, as is the case of the SM, if one demands $g_5^2 \sim \pi R$. Using $kR \sim 10$ and $g_4 \sim 0.5$, one obtains the 5D gauge coupling

$$g_5 \sim 4/\sqrt{k}\,. \quad (85.19)$$

Boundary kinetic terms for the gauge bosons can modify this relation, allowing for larger values of $g_5\sqrt{k}$.

Fermions propagating in a warped extra dimension have 4D massless zero-modes with wavefunctions which vary as $f_0 \sim exp[(1/2-c_f)ky]$, where $c_f k$ is their 5D mass [7,69]. Depending on the free parameter $c_f k$, fermions can be localized either towards the UV-boundary ($c_f > 1/2$) or IR-boundary ($c_f < 1/2$). Since the Higgs boson is localized on the IR-boundary, one can generate exponentially suppressed Yukawa couplings by having the fermion zero-modes localized towards the UV-boundary, generating naturally the light SM fermion spectrum [7]. A large overlap with the wavefunction of the Higgs is needed for the top quark, in order to generate its large mass, thus requiring it to be localized towards the IR-boundary. In conclusion, the large mass hierarchies present in the SM fermion spectrum can be easily obtained in warped models via suitable choices of the order-one parameters c_f [70]. In these scenarios, deviations in flavor physics from the SM predictions are expected to arise from flavor-changing KK gluon couplings [71], putting certain constraints on the parameters of the models and predicting new physics effects to be observed in B-physics processes (see, for example, [72,73]).

The masses of the KK states can also be calculated. One finds [7]

$$m_n \simeq \left(n + \frac{\alpha}{2} - \frac{1}{4}\right)\pi k e^{-\pi kR}\,, \tag{85.20}$$

where $n = 1, 2, ...$ and $\alpha = \{|c_f - 1/2|, 0, 1\}$ for KK fermions, KK gauge bosons and KK gravitons, respectively. Their masses are of order $ke^{-\pi kR} \sim$ TeV (for this reason we refer to these scenarios as TeV-scale extra dimensions). The first KK state of the gauge bosons would be the lightest, while gravitons are expected to be the heaviest.

85.3.1.1 *Models of Electroweak Symmetry Breaking*

Theories in warped extra dimensions can be used to implement symmetry breaking at low energies by boundary conditions (for a review see, for example, [74]). For example, for a $U(1)$ gauge symmetry in the 5D bulk, this can be easily achieved by imposing a Dirichlet boundary condition on the IR-boundary for the gauge-boson field, $A_\mu|_{y=\pi R} = 0$. This makes the zero-mode gauge boson get a mass, given by $m_A = g_4\sqrt{2k/g_5^2}\, e^{-\pi kR}$. A very different situation occurs if the Dirichlet boundary condition is imposed on the UV-boundary, $A_\mu|_{y=0} = 0$. In this case the zero-mode gauge boson disappears from the spectrum. Finally, if a Dirichlet boundary condition is imposed on the two boundaries, one obtains a massless 4D scalar corresponding to the fifth component of the 5D gauge boson, A_5. Thus, different scenarios can be implemented by appropriately choosing the 5D bulk gauge symmetry, $\mathcal{G}_5$, and the symmetries to which it reduces on the UV and IR-boundary, $\mathcal{H}_{UV}$ and $\mathcal{H}_{IR}$, respectively. In all cases the KK spectrum comes in representations of the group $\mathcal{G}_5$.

Among the most interesting scenarios are those called gauge-Higgs unified models, where the Higgs boson appears as the fifth component of a 5D gauge boson, A_5. The Higgs mass is protected by the 5D gauge invariance and can only get a nonzero value from non-local one-loop effects [75]. To guarantee the relation $M_W^2 \simeq M_Z^2 \cos^2\theta_W$, a custodial $SU(2)_V$ symmetry is needed in the bulk and IR-boundary [76]. The simplest realization [77,78] has

$$\begin{aligned}\mathcal{G}_5 &= SU(3)_c \times SO(5) \times U(1)_X,\\ \mathcal{H}_{IR} &= SU(3)_c \times SO(4) \times U(1)_X,\\ \mathcal{H}_{UV} &= G_{SM}.\end{aligned}$$

The Higgs boson gets a potential at the one-loop level that triggers a VEV, breaking the electroweak symmetry. In these models there is a light Higgs boson whose mass can be around 125 GeV, as required by the discovered Higgs boson [79]. This state, as will be explained in Sec. 85.3.2, behaves as a composite pseudo-Nambu-Goldstone boson with couplings that deviate from the SM Higgs [80]. The present experimental determination of the Higgs couplings at the LHC, that agrees with the SM predictions, put important constraints on these scenarios [79]. The lightest KK modes of the model are color fermions with charges $Q = -1/3, 2/3$ and $5/3$ [81].

85.3.1.2 *Constraints from Electroweak Precision Tests*

Models in which the SM gauge bosons propagate in 1/TeV-sized extra dimensions give generically large corrections to electroweak observables. When the SM fermions are confined on a boundary these corrections are universal and can be parameterized by four quantities: $\widehat{S}$, $\widehat{T}$, W and Y, as defined in Ref. [82]. For warped models, where the 5D gauge coupling of Eq. (85.19) is large, the most relevant parameter is $\widehat{T}$, which gives the bound $m_{KK} \gtrsim 10$ TeV [67]. When a custodial symmetry is imposed [76], the main constraint comes from the $\widehat{S}$ parameter, requiring $m_{KK} \gtrsim 3$ TeV, independent of the value of g_5. Corrections to the $Zb_L\bar{b}_L$ coupling can also be important [67], especially in warped models for electroweak symmetry breaking as the ones described above.

85.3.1.3 *Kaluza-Klein Searches*

The main prediction of 1/TeV-sized extra dimensions is the presence of a discretized KK spectrum, with masses around the TeV scale, associated with the SM fields that propagate in the extra dimension.

In the RS model [3], only gravity propagates in the 5D bulk. Experimental searches have been performed for the lightest KK graviton through its decay to a variety of SM particle-antiparticle pairs. The results are usually interpreted in the plane of the dimensionless coupling k/M_P versus m_1, where M_P is the reduced Planck mass defined previously and m_1 is the mass of the lightest KK excitation of the graviton. Since the AdS curvature $\sim k$ cannot exceed the cut-off scale of the model, which is estimated to be $\ell_5^{1/3} M_5$ [38], one must demand $k \ll \sqrt{2\ell_5} M_P \simeq 40 M_P$.

The most stringent limits currently arise from LHC searches for resonances in the dilepton and diphoton final states, using 13 TeV collisions. Best sensitivities are obtained in the $\gamma\gamma$ final state, which is quite powerful since it has a branching fraction twice that of any individual lepton flavor. The CMS analysis [41] of 36 fb^{-1}of 13 TeV data excludes KK gravitons below 2.3 to 4.6 TeV, depending on the value of the coupling k/M_P, which is varied between 0.01 and 0.2, while ATLAS [83] uses the full 139 fb^{-1}and provides a lower limit on the KK graviton mass of 4.6 TeV for the coupling parameter 0.1. The CMS [42] dilepton analyses, combining results from the ee and $\mu\mu$ channels, exclude KK gravitons with masses 2.47–4.78 TeV for k/M_P values of 0.01–0.1. The ATLAS [84] analysis of 139 fb^{-1}of Run 2 data does not include a RS KK graviton interpretation of the results. Less stringent limits on the KK graviton mass can be derived from analyses of the dijet [85, 86], HH [87–90], and VV [91–94] final states, where V can represent either a W or Z boson.

In warped extra-dimensional models in which the SM fields propagate in the 5D bulk, the couplings of the KK graviton to $ee/\mu\mu/\gamma\gamma$ are suppressed [95], and the above bounds do not apply. Furthermore, the KK graviton is the heaviest KK state (see Eq. (85.20)), and therefore experimental searches for KK gauge bosons and fermions are more appropriate discovery channels in these scenarios. For the scenarios discussed above in which only the Higgs boson and the top quark are localized close to the IR-boundary, the KK gauge bosons mainly decay into top quarks, longitudinal W/Z bosons, and Higgs bosons. Couplings to light SM fermions are suppressed by a factor $g/\sqrt{g_5^2 k} \sim 0.2$ [7] for the value of Eq. (85.19) that is considered from now on. Searches have been made for evidence of the lightest KK excitation of the gluon, through its decay to $t\bar{t}$ pairs. The searches take into account the natural KK gluon width, which is typically $\sim 15\%$ of its mass. The decay of a heavy particle to $t\bar{t}$ would tend to produce highly boosted top (anti-)quarks in the final state. Products of the subsequent top decays would therefore tend to be close to each other in the detector. In the case of $t \to Wb \to jjb$ decays, the three jets could overlap with one another and not be individually reconstructed with the standard jet algorithms, while $t \to Wb \to \ell\nu b$ decays could result in the lepton failing standard isolation requirements due to its proximity to the b-jet; in both cases, the efficiency for properly reconstructing the final state would fall as the mass of the original particle increases. To avoid the loss in sensitivity which would result, a number of techniques, known generally as "top quark tagging" [96, 97], have been developed to reconstruct and identify highly boosted top quarks, for example by using a

single "wide" jet to contain all the decay products of a hadronic top decay. The large backgrounds from QCD jets can then be reduced by requiring the "jet mass" be consistent with that of a top quark, and also by examining the substructure of the wide jet for indication that it resulted from the hadronic decay of a top quark. These techniques are key to extending to very high masses the range of accessible resonances decaying to $t\bar{t}$ pairs. The ATLAS search in 139 fb^{-1}of Run 2 data [98] does not provide a KK interpretation. Dedicated analysis from CMS [99] of 36 fb^{-1} of 13 TeV data combines di-lepton, lepton-plus-jet, and all-hadronic $t\bar{t}$ decays and excludes KK gluons with masses below 4.55 TeV. ATLAS uses all-hadronic [100] and lepton-plus-jet [101] final states to exclude KK gluons up to 3.4 and 3.8 TeV respectively with 36fb^{-1}of 13 TeV data. The results are not directly comparable between the two LHC experiments, since they employ in their respective analyses different implementations of the theoretical model. For masses between 3 and 5 TeV, the cross-section limits are around 20 fb for CMS analysis of 36 fb^{-1}and 30 fb (4 fb) for ATLAS analyses of 36 (139) fb^{-1}.

A gauge boson KK excitation could be also sought through its decay to longitudinal W/Z bosons. Recent analyses from ATLAS [102] (and CMS [103]) with 139 (137) fb^{-1}of 13 TeV data searching for heavy vector resonances decaying to a W or Z boson and a Higgs in the $q\bar{q}b\bar{b}$ final state have set a lower limit on the mass of these KK of 3.2 (3.7) TeV (warped models are equivalent to the Model B considered in the analyses with $g_V \sim g_5\sqrt{k}$). The decay to a pair of intermediate vector bosons has also been exploited to search for KK gravitons in models in which the SM fields propagate in the 5D bulk. The analyses typically reconstruct hadronic W/Z decays using variants of the boosted techniques mentioned previously. An ATLAS analysis [104] combines leptonic and hadronic final states from the KK graviton decay $G^* \to VV$, where V can represent either a W or Z boson, exclude KK gravitons with masses below 2.3 TeV, for a value of $k/M_P = 1$. CMS VV analysis [105] also provides cross section limits in the context of bulk gravitons; however, a maximum value of $k/M_P = 0.5$ is presented, for which no mass exclusion is possible using the 36 fb^{-1}of 13 TeV data.

The lightest KK states are, in certain models, the partners of the top quark. For example, in 5D composite Higgs models these are colored states with charges $Q = -1/3, 2/3$ and $5/3$ (arising from $SU(2)_L$ doublets with $Y = 7/6, 1/6$), and masses expected to be below the TeV [81]. They can be either singly or pair-produced, and mainly decay into a combination of W/Z with top/bottom quarks [106–109]. An exhaustive review of these searches can be found in Ref. [110]. Of particular note, the $Q = 5/3$ state decays mainly into $W^+t \to W^+W^+b$, giving a very clean signature of a pair of same-sign leptons in the final state. An analysis by ATLAS [111] searching in the lepton-plus-jets final state for evidence of pair production of the $Q = 5/3$ state provides a lower mass limit of 1.25 TeV. A CMS analysis [112] searching for pair production of the $Q = 5/3$ state using both lepton-plus-jets and same sign lepton final states excludes masses below 1.3 TeV. Both LHC experiments have searched for pair production of vector-like quarks T and B of charges $Q = 2/3$ and $-1/3$ respectively, assuming the allowable decays are $T \to Wb/Zt/Ht$ and $B \to Wt/Zb/Hb$. In each case, it is assumed the branching fractions of the three decay modes sum to unity, but the individual branching fractions, which are model-dependent, are allowed to vary within this constraint. Both ATLAS [113] and CMS [114] obtain lower limits on the mass of the T and B vector-like quarks up to 1.5 TeV.

Recent analyses from ATLAS [115] and CMS [116] also search for a single top partner production, the cross section for which is model-dependent [117] but does not carry the kinematic penalty for producing two heavy objects.

85.3.2 *Connection with Strongly Coupled Models via the AdS/CFT Correspondence*

The AdS/CFT correspondence [8] provides a connection between warped extra-dimensional models and strongly-coupled theories in ordinary 4D. Although the exact connection is only known for certain cases, the AdS/CFT techniques have been very useful to obtain, at the qualitative level, a 4D holographic description of the various phenomena in warped extra-dimensional models [11].

The connection goes as follows. The physics of the bulk AdS$_5$ models can be interpreted as that of a 4D conformal field theory (CFT) which is strongly coupled. The extra-dimensional coordinate y plays the role of the renormalization scale μ of the CFT by means of the identification $\mu \equiv ke^{-ky}$. Therefore the UV-boundary corresponds in the CFT to a UV cut-off scale at $\Lambda_{UV} = k \sim M_P$, breaking explicitly conformal invariance, while the IR-boundary can be interpreted as a spontaneous breaking of the conformal symmetry at energies $ke^{-k\pi R} \sim$ TeV. Fields localized on the UV-boundary are elementary fields external to the CFT, while fields localized on the IR-boundary and KK states corresponds to composite resonances of the CFT. Furthermore, local gauge symmetries in the 5D models, $\mathcal{G}_5$, correspond to global symmetries of the CFT, while the UV-boundary symmetry can be interpreted as a gauging of the subgroup $\mathcal{H}_{UV}$ of $\mathcal{G}_5$ in the CFT. Breaking gauge symmetries by IR-boundary conditions corresponds to the spontaneous breaking $\mathcal{G}_5 \to \mathcal{H}_{IR}$ in the CFT at energies $\sim ke^{-k\pi R}$. Using this correspondence one can easily derive the 4D massless spectrum of the compactified AdS$_5$ models. One also has the identification $k^3/M_5^3 \approx 16\pi^2/N^2$ and $g_5^2 k \approx 16\pi^2/N^r$ ($r = 1$ or 2 for CFT fields in the fundamental or adjoint representation of the gauge group), where N plays the role of the number of colors of the CFT. Therefore the weak-coupling limit in AdS$_5$ corresponds to a large-N expansion in the CFT.

Following the above AdS/CFT dictionary one can understand the RS solution to the hierarchy problem from a 4D viewpoint. The equivalent 4D model is a CFT with a TeV mass gap and a Higgs boson emerging as a composite state. In the particular case where the Higgs is the fifth-component of the gauge-boson, A_5 [118], this corresponds to models, similar to those proposed in Ref. [119, 120], where the Higgs is a composite pseudo-Nambu-Goldstone boson arising from the spontaneous breaking $\mathcal{G}_5 \to \mathcal{H}_{IR}$ in the CFT. The AdS/CFT dictionary tells us that KK states must behave as composite resonances. For example, if the SM gauge bosons propagate in the 5D bulk, the lowest KK $SU(2)_L$-gauge boson must have properties similar to those of the Techni-rho ρ_T [110] with a coupling to longitudinal W/Z bosons given by $g_5\sqrt{k} \approx g_{\rho_T}$, while the coupling to elementary fermions is $g^2/\sqrt{g_5^2 k} \approx g^2 F_{\rho_T}/M_{\rho_T}$.

Fermions in compactified AdS$_5$ also have a simple 4D holographic interpretation. The 4D massless mode described in Sec. 85.3.1 corresponds to an external fermion ψ_i linearly coupled to a fermionic CFT operator $\mathcal{O}_i$: $\mathcal{L}_{\rm int} = \lambda_i \bar{\psi}_i \mathcal{O}_i + h.c.$. The dimension of the operator $\mathcal{O}_i$ is related to the 5D fermion mass according to $\mathrm{Dim}[\mathcal{O}_i] = |c_f + 1/2| - 1$. Therefore, by varying c_f one varies $\mathrm{Dim}[\mathcal{O}_i]$, making the coupling λ_i irrelevant ($c_f > 1/2$), marginal ($c_f = 1/2$) or relevant ($c_f < 1/2$). When irrelevant, the coupling is exponentially suppressed at low energies, and then the coupling of ψ_i to the CFT (and eventually to the composite Higgs) is very small. When relevant, the coupling grows in the IR and become as large as g_5 (in units of k), meaning that the fermion is as strongly coupled as the CFT states [77]. In this latter case ψ_i behaves as a composite fermion.

85.3.3 *Flat Extra Dimensions*

Models with quantum gravity at the TeV scale, as in the ADD scenario, can have extra (flat) dimensions of 1/TeV size, as happens in string scenarios (see, for example, [121]). All SM fields may propagate in these extra dimensions, leading to the possibility of observing their corresponding KK states.

A simple example is to assume that the SM gauge bosons propagate in a flat five-dimensional orbifold S^1/Z_2 of radius R, with the fermions localized on a 4D boundary. The KK gauge bosons behave as sequential SM gauge bosons with a coupling to fermions enhanced by a factor $\sqrt{2}$ [121]. The experimental limits on such sequential gauge bosons could therefore be recast as limits on KK gauge bosons. Such an interpretation of the ATLAS 7 TeV dilepton analysis [122] yielded the bound $1/R > 4.16$ TeV, while a CMS 8 TeV search with a lepton and missing transverse energy in the final state [123] give $1/R > 3.4$ TeV. Indirect bounds from LEP2 require however $1/R \gtrsim 6$ TeV [82, 124], a bound that can considerably improve in the future by high-energy measurements of the dilepton invariant mass spectrum from Drell-Yan processes

at the LHC [125]. More recent LHC limits on leptonically decaying gauge bosons [84, 126–129] are not interpreted as bounds on $1/R$ by the collaborations, but the published results allow for independent derivation of such bounds.

An alternative scenario, known as Universal Extra Dimensions (UED) [130] (for a review see, for example, [131]), assumes that all SM fields propagate universally in a flat orbifold S^1/Z_2 with an extra Z_2 parity, called KK-parity, that interchanges the two boundaries. In this case, the lowest KK state is stable and is a Dark Matter candidate. At colliders, the KK particles would have to be created in pairs, and would then cascade decay to the lightest KK particle, which would be stable and escape detection. The UED mass-spectrum depends not only on the extra-dimensional radius R, but also on the cut-off of the 5D theory Λ, since quantum corrections sensitive to ΛR induce mass-splittings between the KK states. Experimental signatures, such as jets or leptons and $\not{E}_T$, would be similar to those of typical R-parity conserving SUSY searches. An interpretation of the recent LHC experimental SUSY searches for UED models has been presented in Refs. [132,133]. A lower bound $1/R > 1.4 - 1.5$ TeV was derived for ΛR in the range $5 - 35$ [132]. A recent analysis is given in Ref. [134] where it is shown that the minimal UED model is ruled out when LHC data is combined with Dark Matter relic density data. Extensions to the minimal UED model where boundary terms are included can however be compatible with experiments [134].

Finally, realistic models of electroweak symmetry breaking can also be constructed with flat extra spatial dimensions, similarly to those in the warped case, requiring, however, the presence of sizeable boundary kinetic terms [135]. There is also the possibility of breaking supersymmetry by boundary conditions [136]. Models of this type could explain naturally the presence of a Higgs boson lighter than $M_D \sim$ TeV (see, for example, [137–139]).

86. W'-Boson Searches

Revised October, 2021 by B.A. Dobrescu (FNAL) and S. Willocq (U. Massachusetts).

The W' boson is a massive hypothetical particle of spin 1 and electric charge ±1, which is a color singlet and is predicted in various extensions of the Standard Model (SM).

86.1 W' couplings to quarks and leptons

The Lagrangian terms describing the couplings of a W'^{+} boson to fermions are given by

$$\frac{W'^{+}_{\mu}}{\sqrt{2}}\left[\overline{u}_i\left(C^R_{q_{ij}}P_R+C^L_{q_{ij}}P_L\right)\gamma^\mu d_j+\overline{\nu}_i\left(C^R_{\ell_{ij}}P_R+C^L_{\ell_{ij}}P_L\right)\gamma^\mu e_j\right]. \tag{86.1}$$

Here, u, d, ν, and e are the SM fermions in the mass eigenstate basis, $i, j = 1, 2, 3$ label the fermion generation, and $P_{R,L} = (1 \pm \gamma_5)/2$. The coefficients $C^L_{q_{ij}}$, $C^R_{q_{ij}}$, $C^L_{\ell_{ij}}$, and $C^R_{\ell_{ij}}$ are complex dimensionless parameters. If $C^R_{\ell_{ij}} \neq 0$, then the ith generation includes a right-handed neutrino. Using this notation, the SM W couplings are $C^L_q = gV_{\rm CKM}$, $C^L_\ell = g \approx 0.63$ and $C^R_q = C^R_\ell = 0$.

Unitarity considerations imply that the W' boson is associated with a spontaneously-broken gauge symmetry. This is true even when it is a composite particle (*e.g.* $\rho^{\pm}$-like bound states [1]) if its mass is much smaller than the compositeness scale, or a Kaluza-Klein mode in theories where the W boson propagates in extra dimensions [2]. The simplest extension of the electroweak gauge group that includes a W' boson is $SU(2)_1 \times SU(2)_2 \times U(1)$, but larger groups are encountered in some theories. A generic property of these gauge theories is that they also include a Z' boson [3]; the W'-to-Z' mass ratio is often a free parameter.

A tree-level mass mixing may be induced between the electrically-charged gauge bosons. Upon diagonalization of their mass matrix, the W-to-Z mass ratio and the couplings of the observed W boson are shifted from the SM values. Their measurements imply that the mixing angle, θ_+, between the gauge eigenstates must be smaller than about 10^{-2} [4]. In certain theories the mixing is negligible (*e.g.*, due to a new parity [5]), even when the W' mass is near the electroweak scale. Note that $SU(2)$ gauge invariance suppresses the kinetic mixing between the W and W' bosons (in contrast to the case of a Z' boson [3]).

The W' coupling to WZ is fixed by Lorentz and gauge invariances, and to leading order in θ_+ is given by [6]

$$\frac{g\,\theta_+\,i}{\cos\theta_W}\left[W'^{+}_{\mu}\left(W^-_\nu Z^{\nu\mu}+Z_\nu W^{-\mu\nu}\right)+Z^\nu W^{-\mu}W'^{+}_{\nu\mu}\right]+\text{H.c.}, \tag{86.2}$$

where $W^{\mu\nu} \equiv \partial^\mu W^\nu - \partial^\nu W^\mu$, etc. The θ_W dependence shown here corrects the one given in Ref. [7], which has been referred to as the Extended Gauge Model by the experimental collaborations. The W' coupling to Wh^0, where h^0 is the SM Higgs boson, is

$$-\,\xi_h\,g_{W'}\,M_W\;W'^{+}_{\mu}\,W^{\mu-}h^0+\text{H.c.}, \tag{86.3}$$

where $g_{W'}$ is the gauge coupling of the W' boson, and the coefficient ξ_h satisfies $\xi_h \leq 1$ in simple Higgs sectors [6].

In models based on the "left-right symmetric" gauge group [8], $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$, the SM fermions that couple to the W boson transform as doublets under $SU(2)_L$ while the other fermions transform as doublets under $SU(2)_R$. Consequently, the W' boson couples primarily to right-handed fermions; its coupling to left-handed fermions arises due to the θ_+ mixing, so that C^L_q is proportional to the CKM matrix and its elements are much smaller than the diagonal elements of C^R_q. Generically, C^R_q does not need to be proportional to $V_{\rm CKM}$.

There are many other models based on the $SU(2)_1 \times SU(2)_2 \times U(1)$ gauge symmetry. In the "alternate left-right" model [9], all the couplings shown in Eq. (86.1) vanish, but there are some new fermions such that the W' boson couples to pairs involving a SM fermion and a new fermion. In the "ununified SM" [10], the left-handed quarks are doublets under one $SU(2)$, and the left-handed leptons are doublets under a different $SU(2)$, leading to a mostly leptophobic W' boson: $C^L_{\ell_{ij}} \ll C^L_{q_{ij}}$ and $C^R_{\ell_{ij}} = C^R_{q_{ij}} = 0$. Fermions of different generations may also transform as doublets under different $SU(2)$ gauge groups [11]. In particular, the couplings to third generation quarks may be enhanced [12].

It is also possible that the W' couplings to SM fermions are highly suppressed. For example, if the quarks and leptons are singlets under one $SU(2)$ [13], then the couplings are proportional to the tiny mixing angle θ_+. Similar suppressions may arise if some vectorlike fermions mix with the SM fermions [14].

Gauge groups that embed the electroweak symmetry, such as $SU(3)_W \times U(1)$ or $SU(4)_W \times U(1)$, also include one or more W' bosons [15].

86.2 Collider searches

At hadron colliders, W' bosons can be detected through resonant pair production of fermions (f and f') or electroweak bosons with a net electric charge equal to ±1. When W' has a width much smaller than its mass ($\Gamma_{W'}/M_{W'} \lesssim 7\%$), the contribution of the s-channel W' exchange to the total rate for $pp \to f\bar{f}'X$, where X is any final state, may be approximated by the branching fraction $B(W' \to f\bar{f}')$ times the production cross section [16], which may be written as

$$\sigma\left(pp\to W'X\right) \simeq \frac{\pi}{6s}\sum_{i,j}\left[(C^L_{q_{ij}})^2+(C^R_{q_{ij}})^2\right]w_{ij}\left(M^2_{W'}/s, M_{W'}\right). \tag{86.4}$$

The functions w_{ij} include the information about proton structure, and are given to leading order in α_s by

$$w_{ij}(z,\mu) = \int_z^1 \frac{dx}{x}\left[u_i(x,\mu)\,\overline{d}_j\left(\frac{z}{x},\mu\right)+\overline{u}_i(x,\mu)\,d_j\left(\frac{z}{x},\mu\right)\right], \tag{86.5}$$

where $u_i(x,\mu)$ and $d_i(x,\mu)$ are the parton distributions inside the proton at the factorization scale μ and parton momentum fraction x for the up- and down-type quarks of the ith generation, respectively. QCD corrections to W' production are sizable (they also include quark-gluon initial states), but preserve the above factorization of couplings at next-to-leading order [17].

The most commonly studied W' signal consists of a high-momentum electron or muon and large missing transverse momentum. The signal transverse mass distribution forms a Jacobian peak with its endpoint at $M_{W'}$ (see Fig. 1 (top) of Ref. [18]). Given that the branching fractions for $W' \to e\nu$ and $W' \to \mu\nu$ could be very different, the results in these channels should be presented separately. Searches in these channels often implicitly assume that the left-handed couplings vanish (no interference between W and W'), and that the right-handed neutrino is light compared to the W' boson and escapes the detector. An example of parameter values that satisfy these assumptions is $C^R_q = gV_{\rm CKM}$, $C^R_\ell = g$, $C^L_q = C^L_\ell = 0$, which define a model that preserves lepton universality and predicts the same total cross section as the Sequential SM used in many W' searches. However, if a W' boson were discovered and the final state fermions have left-handed helicity, then the effects of $W - W'$ interference could be observed [19], providing information about the W' couplings. The effects of the W' width on interference are discussed in Ref. [20].

In the $e\nu$ channel, the ATLAS and CMS collaborations set limits on the W' production cross section times branching fraction $\sigma \times B$ (and thus indirectly on the W' couplings). These limits are set for $M_{W'}$ in the $0.15-7$ TeV range and are based on 139 fb^{-1} at $\sqrt{s} = 13$ TeV [18,21], with the most stringent limits reproduced in Fig. 86.1. ATLAS sets the strongest mass limit $M_{W'} > 6.0$ TeV in the Sequential SM (all limits in this mini-review are at the 95% CL). The coupling limits are much weaker for $M_{W'} < 150$ GeV, a range last explored with the Tevatron at $\sqrt{s} = 1.8$ TeV [22].

In the $\mu\nu$ channel, ATLAS and CMS set rate limits for $M_{W'}$ in the $0.15-7$ TeV range [18,21], with the strongest mass lower limit of 5.6 TeV in the Sequential SM set by CMS [21] using 137 fb^{-1} of $\sqrt{s} = 13$ TeV data, as shown in Fig. 86.1. When combined with the $e\nu$ channel assuming lepton universality, the upper limit on the $\sqrt{s} = 13$ TeV cross section times branching fraction to $\ell\nu$ varies between 0.05 and 2.1 fb for $M_{W'}$ values between 1 and 6 TeV [18]. Only weak limits on $W' \to \mu\nu$ exist for $M_{W'} <$ 150 GeV [25]. Note that masses of the order of the electroweak

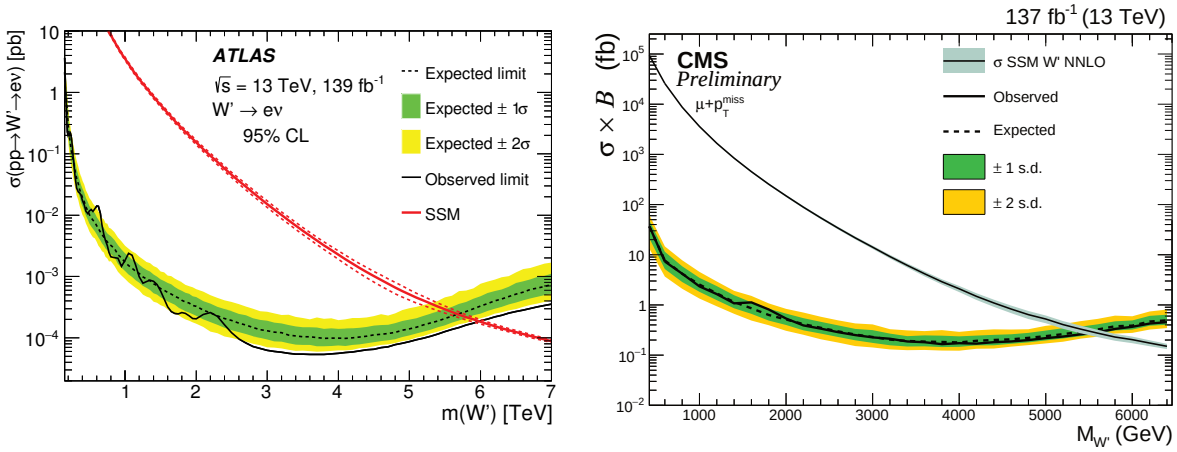

Figure 86.1: Upper limit on $\sigma(pp \to W'X) \times B(W' \to \ell\nu)$ in the $e\nu$ channel from ATLAS [18] (left) and the $\mu\nu$ channel from CMS [21] (right). The red (black) line shows the theoretical prediction in the Sequential SM in the $e\nu$ ($\mu\nu$) channel.

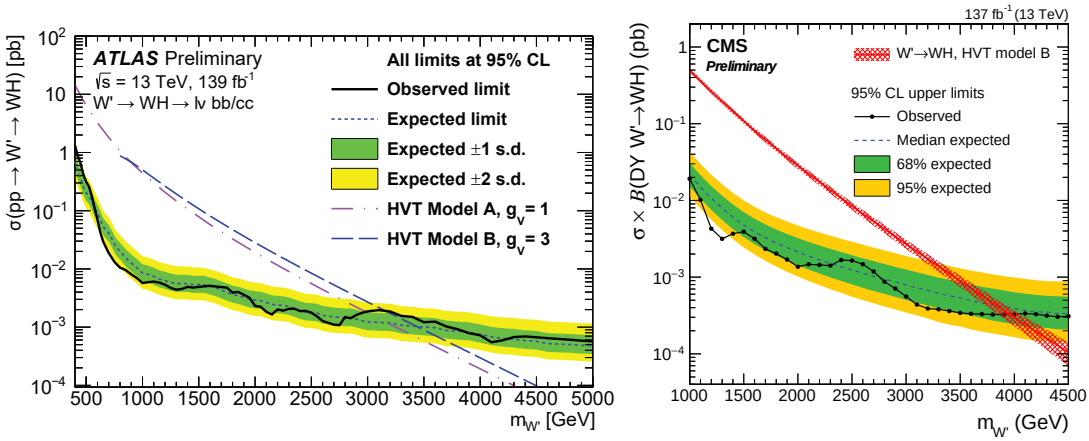

Figure 86.2: Upper limits on W' production cross section times branching fraction into a W and a SM Higgs boson decaying into heavy-flavor quarks, from ATLAS [23] (left) and CMS [24] (right).

scale are interesting from a theoretical point of view, while lepton universality does not necessarily apply to a W' boson.

Searches for $W' \to \tau\nu$ have been performed at 13 TeV by CMS with 36 fb^{-1} [26], and by ATLAS with 139 fb^{-1} [27]. Limits are set on $\sigma \times B$ for $M_{W'}$ between 0.4 and 6 TeV. A mass lower limit of 5.0 TeV is set in the Sequential SM, and the upper limit on the cross section times branching fraction to $\tau\nu$ at 13 TeV varies between 0.4 and 9 fb for $M_{W'}$ values between 1 and 5 TeV [27].

The W' decay into a charged lepton and a right-handed neutrino, ν_R, may also be followed by the ν_R decay through a virtual W' boson into a charged lepton and two quark jets. The CMS [28] and ATLAS [29] searches in the $eejj$ and $\mu\mu jj$ channels have set limits at $\sqrt{s} = 13$ TeV on the cross section times branching fractions as a function of the ν_R mass and of $M_{W'}$. No requirement is placed on the charge of the lepton pair. A related W' search in the $\tau\tau jj$ channel with hadronic τ decays was also performed by CMS [30].

The $t\bar{b}$ channel is particularly important because a W' boson that couples only to right-handed fermions cannot decay to leptons when the right-handed neutrinos are heavier than $M_{W'}$. Additional motivations are provided by a W' boson with enhanced couplings to the third generation [12], and by a leptophobic W' boson. The usual signature for $W' \to t\bar{b}$ consists of a leptonically-decaying W boson and two b-jets. Recent studies have also incorporated the fully hadronic decay channel for $M_{W'} \gg m_t$ with the use of jet substructure techniques to tag highly boosted top-jets. For a detailed discussion of this channel, see Ref. [31].

Searches for dijet resonances may be used to set limits on $W' \to q\bar{q}'$. ATLAS [32] and CMS [33] provide similar coverage in the $\sim$ 1.5−8 TeV mass range with 139 and 137 fb^{-1} of data, respectively, collected at $\sqrt{s} = 13$ TeV. Interpretation in terms of W' decays with 139 fb^{-1} of 13 TeV data yields a W' mass lower limit of 4.0 TeV in the Sequential SM [32]. For masses in the range $\sim 0.5 - 1.5$ TeV, analyses based on jets reconstructed online provide the best sensitivity because they circumvent trigger bandwidth limitations [34, 35]. For W' masses below ~ 0.5 TeV, the best limits are set in novel analyses exploiting boosted technologies and initial state radiation [36–39]. Cross-section limits for W' masses below ~ 1.5 TeV can be derived from the dijet limits on Z' bosons summarized in Ref. [3].

In some theories [5] the W' couplings to SM fermions are suppressed by discrete symmetries. W' production then occurs in pairs, through a photon or Z boson. The decay modes are model-dependent and often involve other new particles. The ensuing collider signals arise from cascade decays and often include missing transverse momentum or boosted multi-jet topologies. An example is a search performed by CMS [40] for W' decays into a vector-like quark and a top or a bottom quark. The final state studied in this analysis involves a boosted SM Higgs boson or Z, as well as a $t\bar{t}$ or $b\bar{b}$ pair, with all heavy particles decaying into jets.

Searches for WZ resonances at the LHC have focused on the process $pp \to W' \to WZ$ with the production mainly from $u\bar{d} \to W'$, assuming SM-like couplings to quarks. ATLAS and CMS have set the upper limits on the $W'WZ$ coupling for $M_{W'}$ in the $0.2 - 5.0$ TeV range with a combination of fully leptonic, semi-leptonic and fully hadronic channels with ~ 36 fb^{-1} at 13 TeV [41, 42] (see also Ref. [31]). More recent constraints with

77–139 fb^{-1} at 13 TeV were also set in individual channels by ATLAS [43, 44] and CMS [24, 45–47]. The strongest lower limit on the W' mass is set by ATLAS [44] in the semi-leptonic channel with a lower limit on $M_{W'}$ of 3.9 TeV [44] in the context of the Heavy Vector Triplet (HVT) weakly-coupled scenario A [48]. A fermiophobic W' boson that couples to WZ may be produced at hadron colliders in association with a Z boson, or via WZ fusion. This would give rise to $(WZ)Z$ and $(WZ)jj$ final states [49]. Results of the search for the latter are reported in Refs. [24,41,44,46].

W' bosons have also been searched for in final states with a W boson and a SM Higgs boson in the channels $W \to \ell\nu$ or $W \to q\bar{q}'$ and $h^0 \to b\bar{b}$ by ATLAS [23, 50] and CMS [24, 51] with 36–139 fb^{-1} at $\sqrt{s} = 13$ TeV. Cross-section limits are set for W' masses between 0.4 and 5.0 TeV. The ATLAS and CMS 13 TeV analyses with $W \to \ell\nu$ set the most stringent upper limits on the cross section at low and high $M_{W'}$, respectively, as shown in Fig. 86.2.

At lepton colliders, W' bosons may be produced in pairs via their photon coupling, which is model independent. At LEP-II, although dedicated searches for W' bosons have not been performed, the large cross section for $e^+e^- \to \gamma^* \to W'^+W'^-$ and small backgrounds suggest that any W' is ruled out up to the kinematic limit, $M_{W'} < \sqrt{s}/2 \approx 105$ GeV, for most decay modes. Sensitivity to $M_{W'}$ above $\sqrt{s}$ could be achieved [52] using the $e^+e^- \to \gamma\nu\bar{\nu}$ process via a t-channel W' exchange, if the W' coupling to $e\nu$ is large enough.

86.3 Low-energy constraints

The properties of W' bosons are also constrained by measurements of processes at energies much below $M_{W'}$. The bounds on $W - W'$ mixing [4] are mostly due to the change in W properties compared to the SM. Limits on deviations in the ZWW couplings provide a leading constraint for fermiophobic W' bosons [14].

Constraints arising from low-energy effects of W' exchange are strongly model-dependent. If the W' couplings to quarks are not suppressed, then box diagrams involving a W and a W' boson contribute to neutral meson-mixing. In the case of W' couplings to right-handed quarks as in the left-right symmetric model, the limit from $K_L - K_S$ mixing is severe: $M_{W'} > 2.9$ TeV for $C_q^R = gV_{\rm CKM}$ [53]. However, if no correlation between the W' and W couplings is assumed, then the limit on $M_{W'}$ may be significantly relaxed [54].

W' exchange also contributes at tree level to various low-energy processes. In particular, it would impact the measurement of the Fermi constant G_F in muon decay, which in turn would change the predictions of many other electroweak processes. A recent test of parity violation in polarized muon decay [55] has set limits of about 600 GeV on $M_{W'}$, assuming W' couplings to right-handed leptons as in left-right symmetric models and a light ν_R. There are also W' contributions to the neutron electric dipole moment, β decays, and other processes [4].

If right-handed neutrinos have Majorana masses, then there are tree-level contributions to neutrinoless double-beta decay, and a limit on $M_{W'}$ versus the ν_R mass may be derived [56]. For ν_R masses below a few GeV, the W' boson contributes to leptonic and semileptonic B meson decays, so that limits may be placed on various combinations of W' parameters [54]. For ν_R masses below ∼30 MeV, the most stringent constraints on $M_{W'}$ are due to the limits on ν_R emission from supernovae.

87. Z'-Boson Searches

Revised October 2021 by B.A. Dobrescu (FNAL) and S. Willocq (U. Massachusetts).

The Z' boson is a massive, electrically-neutral and color-singlet hypothetical particle of spin 1. This particle is predicted in many extensions of the Standard Model (SM) and has been the object of extensive phenomenological studies [1].

87.1 Z' boson couplings

The couplings of a Z' boson to the first-generation fermions are given by

$$Z'_\mu \left(g_u^L\, \overline{u}_L \gamma^\mu u_L + g_d^L\, \overline{d}_L \gamma^\mu d_L + g_u^R\, \overline{u}_R \gamma^\mu u_R + g_d^R\, \overline{d}_R \gamma^\mu d_R + g_\nu^L\, \overline{\nu}_L \gamma^\mu \nu_L + g_e^L\, \overline{e}_L \gamma^\mu e_L + g_e^R\, \overline{e}_R \gamma^\mu e_R \right), \tag{87.1}$$

where u, d, ν, e are the quark and lepton fields in the mass eigenstate basis, and the coefficients g_u^L, g_d^L, g_u^R, g_d^R, g_ν^L, g_e^L, g_e^R are real dimensionless parameters. If the Z' couplings to quarks and leptons are generation-independent, then these seven parameters describe the couplings of the Z' boson to all SM fermions. More generally, however, the Z' couplings to fermions are generation-dependent, in which case Eq. (87.1) may be written with generation indices i, $j = 1$, 2, 3 labeling the quark and lepton fields, and with the seven coefficients promoted to 3×3 Hermitian matrices (*e.g.*, $g_{e\,ij}^L\, \overline{e}_L^i \gamma^\mu e_L^j$, where e_L^2 is the left-handed muon, etc.).

The parameters describing the Z' boson interactions with quarks and leptons are subject to some theoretical constraints. Quantum field theories that include a heavy spin-1 particle are well behaved at high energies only if that particle is a gauge boson associated with a spontaneously broken gauge symmetry. Quantum effects preserve the gauge symmetry only if the couplings of the gauge boson to fermions satisfy the anomaly equations [2]. Furthermore, the fermion charges under the new gauge symmetry are constrained by the requirement that the quarks and leptons get masses from gauge-invariant interactions with the Higgs fields.

The relation between the couplings displayed in Eq. (87.1) and the gauge charges $z_{f\,i}^L$ and $z_{f\,i}^R$ of the fermions $f = u, d, \nu, e$ involves the unitary 3×3 matrices V_f^L and V_f^R that transform the gauge eigenstate fermions f_L^i and f_R^i, respectively, into the mass eigenstates. The Z' couplings also depend on the mixings of the new gauge boson in the gauge eigenstate basis ($\tilde{Z}'_\mu$). The main mixings are a kinetic mixing $(-\chi/2) B^{\mu\nu} \tilde{Z}'_{\mu\nu}$ with the hypercharge gauge boson B^μ (χ is a dimensionless parameter), and a mass mixing $\delta M^2\, \tilde{Z}^\mu \tilde{Z}'_\mu$ with the linear combination ($\tilde{Z}_\mu$) of neutral bosons that couples as the SM Z boson [3]. Since both the kinetic and mass mixings shift the mass and couplings of the Z boson, electroweak measurements impose upper limits on χ and $\delta M^2/(M_{Z'}^2 - M_Z^2)$ of the order of 10^{-3} [4]. Keeping only linear terms in these two small quantities, the couplings of the mass-eigenstate Z' boson are given by

$$g_{f\,ij}^L = g_z V_{f\,ii'}^L\, z_{f\,i'}^L \left(V_f^L\right)^\dagger_{i'j} + \frac{e}{c_W} \left(\frac{s_W \chi M_{Z'}^2 + \delta M^2}{2 s_W \left(M_{Z'}^2 - M_Z^2\right)} \sigma_f^3 - \epsilon\, Q_f \right), \tag{87.2}$$

$$g_{f\,ij}^R = g_z V_{f\,ii'}^R\, z_{f\,i'}^R \left(V_f^R\right)^\dagger_{i'j} - \frac{e}{c_W}\, \epsilon\, Q_f, \tag{87.3}$$

where g_z is the new gauge coupling, Q_f is the electric charge of f, e is the electromagnetic gauge coupling, s_W and c_W are the sine and cosine of the weak mixing angle, $\sigma_f^3 = +1$ for $f = u, \nu$ and $\sigma_f^3 = -1$ for $f = d, e$, and

$$\epsilon = \frac{\chi \left(M_{Z'}^2 - c_W^2 M_Z^2\right) + s_W \delta M^2}{M_{Z'}^2 - M_Z^2}. \tag{87.4}$$

The interaction of the Z' boson with a pair of W bosons has the form

$$\left[i \left(W_\mu^- Z'_\nu - W_\nu^- Z'_\mu \right) \partial^\mu W^{+\nu} + \text{H.c.} \right] + i \left(W_\mu^+ W_\nu^- - W_\nu^+ W_\mu^- \right) \partial^\mu Z'^\nu \tag{87.5}$$

with a coefficient of order $M_W^2/M_{Z'}^2$ [5]. The Z' also couples to one SM Higgs boson and one Z boson, $Z'_\mu Z^\mu\, h^0$, with a coefficient of order M_Z.

87.2 Z' models

A simple origin of a Z' boson is a new $U(1)'$ gauge symmetry. In that case, the matricial equalities $z_u^L = z_d^L$ and $z_\nu^L = z_e^L$ are required by the SM $SU(2)_W$ gauge symmetry. Given that the $U(1)'$ interaction is not asymptotically free, the theory may be well-behaved at high energies (*e.g.*, by embedding $U(1)'$ in a non-Abelian gauge group) only if the charges are commensurate numbers, *i.e.* any ratio of charges is a rational number. Satisfying the anomaly equations [6] with rational numbers is highly nontrivial, and typically new fermions charged under $U(1)'$ are necessary.

If the couplings are generation-independent ($V_f^{L,R}$ are then unit matrices in Eq. (87.2)) and the mixings of $\tilde{Z}'$ are negligible, then there are five commensurate couplings: g_u^R, g_d^R, g_e^R, g_q^L ($q = u$ or d), g_l^L ($l = \nu$ or e). Four sets of charges are displayed in Table 87.1, each of them spanned by a free parameter x [6]. The first set, labeled $B - xL$, has charges proportional to the baryon number minus x times the lepton number. These charges allow all SM Yukawa couplings to the Higgs doublet which is neutral under $U(1)_{B-xL}$, so that there is no tree-level $\tilde{Z} - \tilde{Z}'$ mixing. For $x = 1$ one recovers the $U(1)_{B-L}$ group, which is non-anomalous in the presence of one "right-handed neutrino" (a chiral fermion that is a singlet under the SM gauge group) per generation. For $x \neq 1$, it is necessary to include some fermions that are vectorlike (*i.e.* their mass terms are gauge invariant) with respect to the electroweak gauge group and chiral with respect to $U(1)_{B-xL}$. In the particular cases $x = 0$ or $x \gg 1$, the Z' is leptophobic or quark-phobic, respectively.

The second set, $U(1)_{10+x\bar{5}}$, has charges that commute with the representations of the $SU(5)$ grand unified group. Here x is related to the mixing angle between the two $U(1)$ bosons encountered in the $E_6 \to SU(5) \times U(1) \times U(1)$ symmetry breaking patterns of grand unified theories [1,7]. With these charges, two Higgs doublets are typically required to generate masses for both up- and down- type fermions. This set leads to $\tilde{Z} - \tilde{Z}'$ mass mixing at tree level, such that for a Z' mass close to the electroweak scale, the measurements at the Z-pole require some fine tuning between the charges and VEVs of the two Higgs doublets. Vectorlike quarks charged under the electroweak gauge group are required (except for $x = -3$) to make this set anomaly free. The particular cases $x = -3, 1, -1/2$ are usually labeled $U(1)_\chi$, $U(1)_\psi$, and $U(1)_\eta$, respectively. Under the third set, $U(1)_{d-xu}$, the weak-doublet quarks are neutral, and the ratio of u_R and d_R charges is $-x$. For $x = 1$, this is the "right-handed" group $U(1)_R$. For $x = 0$, the charges are those of the E_6-inspired $U(1)_I$ group, which requires new quarks and leptons. Other generation-independent sets of $U(1)'$ charges are given in Ref. [8].

In the absence of new fermions charged under the SM group, the most general generation-independent charge assignment is $U(1)_{q+xu}$, which is a linear combination of hypercharge and $B-L$. Many other anomaly-free solutions exist if generation-dependent charges are allowed. An example is $B - xL_e - yL_\mu + (y-3)L_\tau$, with x, y free parameters. This allows all fermion masses to be generated by Yukawa couplings to a single Higgs doublet, without inducing tree-level flavor-changing neutral current (FCNC) processes. There are also lepton-flavor dependent charges that allow neutrino masses to arise only from operators of high dimensionality [9].

If the $SU(2)_W$-doublet quarks have generation-dependent $U(1)'$ charges, then the mass eigenstate quarks have flavor off-diagonal couplings to the Z' boson (see Eq. (87.1), and note that $V_u^L \left(V_d^L\right)^\dagger$

Table 87.1: Examples of generation-independent $U(1)'$ charges for quarks and leptons. The parameter x is an arbitrary rational number. Gauge anomaly cancellation requires certain new fermions [6].

fermion	$U(1)_{B-xL}$	$U(1)_{10+x\bar{5}}$	$U(1)_{d-xu}$	$U(1)_{q+xu}$
(u_L, d_L)	$1/3$	$1/3$	0	$1/3$
u_R	$1/3$	$-1/3$	$-x/3$	$x/3$
d_R	$1/3$	$-x/3$	$1/3$	$(2-x)/3$
(ν_L, e_L)	$-x$	$x/3$	$(-1+x)/3$	-1
e_R	$-x$	$-1/3$	$x/3$	$-(2+x)/3$

is the CKM matrix). These are severely constrained by measurements of FCNC processes, which in this case are mediated at tree-level by Z' boson exchange [10]. The constraints are relaxed if the first and second generation charges are the same, although they are increasingly tightened by the measurements of B meson properties [11]. If only the $SU(2)_W$-singlet quarks have generation-dependent $U(1)'$ charges, there is more freedom in adjusting the flavor off-diagonal couplings because the $V^R_{u,d}$ matrices are not observable in the SM.

The anomaly equations for $U(1)'$ could be circumvented only if there is an axion with certain dimension-5 couplings to the gauge bosons. However, such a scenario violates unitarity unless the quantum field theory description breaks down at a scale near $M_{Z'}$ [12]. It is possible, though, that the SM fermions are not charged under the $U(1)'$, but have mass mixing with some vectorlike fermions which are charged under $U(1)'$, implying that the physical fermions have couplings to the Z' [13]. For example, if the only SM quarks that have large mixings with some vectorlike quarks are the b quarks, then the only currently known particles that couple to the Z' would be the physical b quarks.

Z' bosons may also arise from larger gauge groups. These may extend the electroweak group, as in $SU(2)\times SU(2)\times U(1)$, or may embed the electroweak group, as in $SU(3)_W \times U(1)$ [14]. If the larger group is spontaneously broken down to $SU(2)_W \times U(1)_Y \times U(1)'$ at a scale $v_\star \gg M_{Z'}/g_z$, then the above discussion applies up to corrections of order $M^2_{Z'}/(g_z v_\star)^2$. For $v_\star \sim M_{Z'}/g_z$, additional gauge bosons have masses comparable to $M_{Z'}$, including at least a W' boson [14]. If the larger gauge group breaks together with the electroweak symmetry directly to the electromagnetic $U(1)_{\rm em}$, then the left-handed fermion charges are no longer correlated ($z^L_u \neq z^L_d$, $z^L_\nu \neq z^L_e$) and a $Z'W^+W^-$ coupling is induced.

If the electroweak gauge bosons propagate in extra dimensions, then their Kaluza-Klein (KK) excitations include a series of Z' boson pairs. Each of these pairs can be associated with a different $SU(2)\times U(1)$ gauge group in four dimensions. The properties of the KK particles depend strongly on the extra dimensional theory [15]. For example, in universal extra dimensions there is a parity that forces all couplings of Eq. (87.1) to vanish in the case of the lightest KK bosons, while allowing couplings to pairs of fermions involving a SM and a heavy vectorlike fermion. There are also 4-dimensional gauge theories (*e.g.* little Higgs with T parity) with Z' bosons exhibiting similar properties. By contrast, in a warped extra dimension, the couplings of Eq. (87.1) may be sizable even when SM fields propagate along the extra dimension.

Z' bosons may also be composite particles. For example, in confining gauge theories [16], the ρ-like bound state is a spin-1 boson that may be interpreted as arising from a spontaneously broken gauge symmetry [17].

87.3 Non-resonant Z' signatures at colliders

In the presence of the couplings shown in Eq. (87.1), the Z' boson may be produced in the s-channel at colliders, and would decay to pairs of fermions. The decay width into a pair of electrons is given by

$$\Gamma\left(Z' \to e^+e^-\right) \simeq \left[\left(g^L_e\right)^2 + \left(g^R_e\right)^2\right] \frac{M_{Z'}}{24\pi}, \qquad (87.6)$$

where small corrections from electroweak loops are not included. The decay width into $q\bar{q}$ is similar, except for an additional color factor of 3, QCD radiative corrections, and fermion mass corrections. Thus, one may compute the Z' branching fractions in terms of the couplings of Eq. (87.1). However, other decay channels, such as WW or a pair of new particles, could have large widths and need to be added to the total decay width.

As mentioned above, there are theories in which the Z' couplings are controlled by a discrete symmetry that forbids decays into a pair of SM particles. Typically, such theories involve several new particles, which may be produced only in pairs and undergo cascade decays through Z' bosons, leading to signals involving missing transverse momentum. Given that the cascade decays depend on the properties of new particles other than the Z' boson (see, *e.g.* Ref. [18]), this case is not discussed further here.

The Z' contribution to the cross sections for $e^+e^- \to f\bar{f}$ proceeds through an s-channel Z' exchange (when $f = e$, there are also t- and u-channel exchanges). For $M_{Z'} < \sqrt{s}$, the Z' appears as an $f\bar{f}$ resonance in the radiative return process where photon emission tunes the effective center-of-mass energy to $M_{Z'}$. The agreement between the LEP-II measurements and the SM predictions implies that either the Z' couplings are smaller than or of order 10^{-2}, or else $M_{Z'}$ is above 209 GeV, the maximum energy of LEP-II. In the latter case, the Z' exchange may be approximated up to corrections of order $s/M^2_{Z'}$ by the contact interactions

$$\frac{g_z^2}{M^2_{Z'} - s}\left[\bar{e}\gamma_\mu\left(z^L_e P_L + z^R_e P_R\right)e\right]\left[\bar{f}\gamma^\mu\left(z^L_f P_L + z^R_f P_R\right)f\right], \qquad (87.7)$$

where $P_{L,R}$ are chirality projection operators, and the relation between Z' couplings and charges (see Eq. (87.2) in the limit where the mass and kinetic mixings are neglected) is used, assuming generation-independent charges. The four LEP collaborations have set limits on the coefficients of such operators for all possible chiral structures and for various combinations of fermions [19]. Thus, one may derive bounds on $(M_{Z'}/g_z)|z^L_e z^L_f|^{-1/2}$ and the analogous combinations of LR, RL and RR charges, which are typically on the order of a few TeV. LEP-II limits were derived [6] on the four sets of charges shown in Table 87.1.

Somewhat stronger bounds can be set on $M_{Z'}/g_z$ for specific sets of Z' couplings if the effects of several operators (87.7) are combined. Dedicated analyses by the LEP collaborations have set limits on Z' bosons for particular values of the gauge coupling (see section 3.5 of Ref. [19]). For example, $M_{Z_{\rm SSM}} > 1.76$ TeV for a "sequential" Z' of same couplings as the SM Z boson, while $M_{Z_\chi} > 0.785$ TeV for the Z' associated with $U(1)_\chi$ assuming a unification condition for the gauge coupling.

87.4 Searches at hadron colliders

Z' bosons with couplings to quarks (see Eq. (87.1)) may be produced at hadron colliders in the s-channel and would show up as resonances in the invariant mass distribution of the decay products. The cross section for producing a Z' boson at the LHC, which then decays to some $f\bar{f}$ final state, takes the form [20]

$$\sigma\left(pp \to Z'X \to f\bar{f}X\right) \simeq \frac{\pi}{6\,s}\sum_q c^f_q\, w_q\left(s, M^2_{Z'}\right) \qquad (87.8)$$

for flavor-diagonal couplings to quarks. Here, we have neglected the interference with the SM contribution to $f\bar{f}$ production, which is a good approximation for a narrow Z' resonance (deviations from the narrow width approximation are discussed in Ref. [21]). The coefficients

$$c^f_q = \left[\left(g^L_q\right)^2 + \left(g^R_q\right)^2\right] B(Z' \to f\bar{f}) \qquad (87.9)$$

contain all the dependence on the Z' couplings, while the functions w_q include all the information about parton distributions and QCD corrections [6, 8]. This factorization holds exactly to NLO and the deviations from it induced at NNLO are very small. Note that the w_u and w_d functions are substantially larger than the w_q functions for the other quarks. Eq. (87.8) also applies to

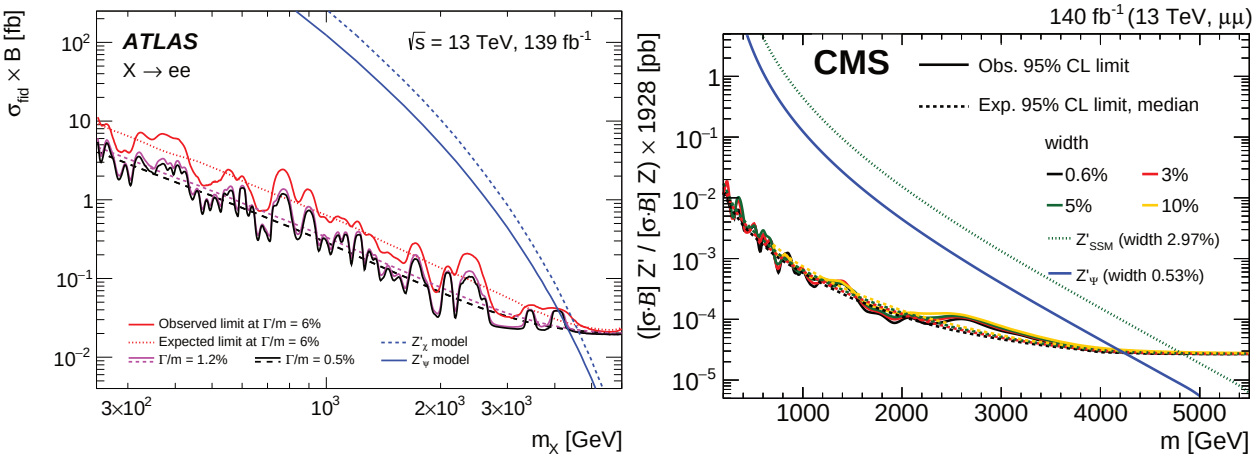

Figure 87.1: Upper limits on the cross section for Z' production times the branching fraction for $Z' \to e^+e^-$ (left panel, set by ATLAS [22]) or $Z' \to \mu^+\mu^-$ (right panel, set by CMS [23]) as a function of $M_{Z'}$. The lines labeled by Z'_ψ and Z'_χ are theoretical predictions for the $U(1)_{10+x\bar{5}}$ models in Table 87.1 with $x = -3$ and $x = +1$, respectively, for g_z fixed by an E_6 unification condition. The $Z'_{\rm SSM}$ line corresponds to Z' couplings equal to those of the Z boson.

the Tevatron, except for changing the pp initial state to $p\bar{p}$, which implies that the $w_q(s, M^2_{Z'})$ functions are replaced by some other functions $\bar{w}_q((1.96\,\text{TeV})^2, M^2_{Z'})$.

It is common to present results of Z' searches as limits on the cross section versus $M_{Z'}$ (see for example Fig. 87.1). An alternative is to plot exclusion curves for fixed $M_{Z'}$ values in the $c^f_u - c^f_d$ planes, allowing a simple derivation of the mass limit within any Z' model. CMS upper limits in the $c^\ell_u - c^\ell_d$ plane ($\ell = e$ or μ) for different $M_{Z'}$ are shown in Ref. [23] (for Tevatron limits, see Refs. [8, 24]).

The discovery of a dilepton resonance at the LHC would determine the Z' mass and width. A measurement of the total cross section would define a band in the $c^\ell_u - c^\ell_d$ plane. Angular distributions can be used to measure several combinations of Z' parameters (angular distributions were used in Ref. [25] to improve the Tevatron sensitivity). Even though the original quark direction in a pp collider is unknown, the leptonic forward-backward asymmetry $A^\ell_{\rm FB}$ can be extracted from the kinematics of the dilepton system, and is sensitive to parity-violating couplings. A fit to the Z' rapidity distribution can distinguish between the couplings to up and down quarks. These measurements, combined with off-peak observables, have the potential to differentiate among various Z' models [26]. In some cases, $A^\ell_{\rm FB}$ may provide discovery sensitivity that is competitive with the mass distribution [27]. The spin of the Z' boson may be determined from angular distributions [28].

Searches for Z' decays into e^+e^- and $\mu^+\mu^-$ by the ATLAS and CMS collaborations [22, 23] have set 95% C.L. upper cross-section limits as low as 0.02 fb (see Fig. 87.1), with the mass lower limits in specific models as high as 4.9 TeV in a single channel. Cross section limits in the dimuon channel for low mass regions, below 200 GeV but not near the Z mass, have been set at the LHC by CMS [29] and LHCb [30].

The $Z' \to \tau^+\tau^-$ decay has been searched for with 36 fb^{-1} of 13 TeV data [31], and a limit $M_{Z'} > 2.4$ TeV has been set in the case of a sequential Z'. Limits on heavy scalars in the $\tau^+\tau^-$ final state, set by ATLAS [32] with 139 fb^{-1} and CMS [33] with 36 fb^{-1} at 13 TeV, can be recast into limits on Z'. Limits in the flavor-violating leptonic final states have also been reported by ATLAS [34] and CMS [35] at 13 TeV, for resonances in the $e^\pm\mu^\mp$, $e^\pm\tau^\mp$ and $\mu^\pm\tau^\mp$ channels.

Final states with higher background, jj, $b\bar{b}$ and $t\bar{t}$, are also important as they probe various combinations of Z' couplings to quarks. Besides the improved sensitivity at masses of several TeV, the LHC searches in the dijet channel have been also extended to masses as low as 10 GeV, through the use of new techniques involving boosted topologies and initial state radiation [37]. Limits from such Z' searches in hadronic final states are summarized in Fig. 87.2.

Searches for the $Z' \to b\bar{b}$ decay have been performed for two production mechanisms. ATLAS [38] and CMS [39] searched for $b\bar{b}$ resonances in 139 fb^{-1} and 137 fb^{-1} of 13 TeV data, respectively, setting limits under the assumption that the Z' boson couples to light quarks and thus is produced in the s-channel. The CMS upper limit on the cross-section times the $Z' \to b\bar{b}$ branching fraction decreases from 40 fb at $M_{Z'} = 1.8$ TeV to 0.4 fb at $M_{Z'} = 8$ TeV. The ATLAS search covered the 1.3 TeV – 5 TeV mass range, setting a lower mass limit of 2.7 TeV for the Z'_{SSM}. Independent of any other couplings, if the Z' couples to the b quark, then it can be produced in association with a $b\bar{b}$ pair, and it decays to a second $b\bar{b}$ pair, which forms a resonance. The cross-section limit for that process, set by ATLAS [40] with 103 fb^{-1} of 13 TeV data, is between 0.1 and 0.2 pb for $M_{Z'}$ in the 1.3 – 3 TeV range. For a vector coupling g_b of Z' to b quarks, *i.e*, $g^L_{d\,33} = g^R_{d\,33} = g_b$ using the notation of Eq. (87.1), the limit is $M_{Z'} > 1.45$ TeV when $g_b = 1$. Searches for the $Z' \to t\bar{t}$ decay are discussed in Ref. [41].

Heavy resonances decaying into Zh^0 with $Z \to \ell^+\ell^-$, $\nu\bar{\nu}$ or $q\bar{q}$ and $h^0 \to b\bar{b}$ have been studied by ATLAS [42, 43] and CMS [44–46] using 13 TeV data. The most stringent constraint on Z' production in the context of the Heavy Vector Triplet (HVT) model weakly-coupled scenario A [47] is set in the semi-leptonic channel, with a mass lower limit of 3.5 TeV [46].

Searches for a Z' boson lighter than the SM Z and which couples to leptons have been performed in the 4-lepton final state. CMS [48] focused on the Z decays into a muon pair followed by the radiation of a Z' boson which decays itself into a muon pair. ATLAS [49] considered the $h^0 \to ZZ'$ and $h^0 \to Z'Z'$ processes followed by the leptonic decays of both Z and Z'.

The $pp \to Z'X \to W^+W^-X$ process has also been searched for at the LHC. The channel where the Z' boson is produced through its couplings to quarks, and the W bosons decay hadronically, has been explored using boosted techniques to analyze the 13 TeV data [50–53] with a mass lower limit of 3.5 TeV in the HVT model A [51]. The Z' boson may also be produced through its couplings to W bosons [54], which has been explored with the use of forward jets consistent with a vector boson fusion event topology [51, 53]. The latter process provides a test of fermiophobic Z' models.

At the Tevatron, the CDF and DØ collaborations have searched for Z' bosons in the e^+e^- [55], $\mu^+\mu^-$ [56], $e^\pm\mu^\mp$ [57], $\tau^+\tau^-$ [58], $t\bar{t}$ [59], jj [60] and W^+W^- [61] final states. These limits have been mostly superseded by the LHC results.

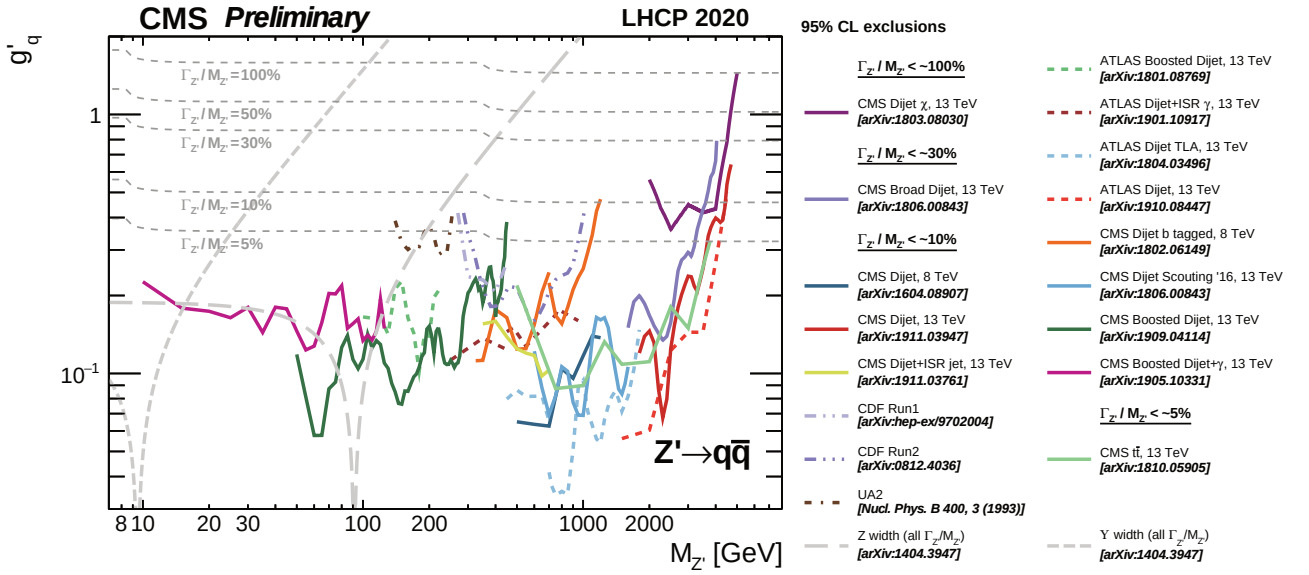

Figure 87.2: Upper limits on the Z' coupling to quarks as a function of $M_{Z'}$ based on various searches performed by the ATLAS, CMS, CDF, and UA2 experiments [36].

87.5 Low-energy constraints

Z' boson properties are also constrained by a variety of low-energy experiments [62]. Polarized electron-nucleon scattering and atomic parity violation are sensitive to electron-quark contact interactions, which get contributions from Z' exchange that can be expressed in terms of the couplings introduced in Eq. (87.1) and M'_Z. Further corrections to the electron-quark contact interactions are induced in the presence of $\tilde{Z}-\tilde{Z}'$ mixing because of the shifts in the Z couplings to quarks and leptons [3]. Deep-inelastic neutrino-nucleon scattering is similarly affected by Z' bosons. Other low-energy observables are discussed in [4]. Viable models with Z' bosons much lighter than the Z boson have been constructed, despite many additional experimental constraints [63]. Limits on the Z' coupling to leptons in the mass range 0.02–10.2 GeV have been set in e^+e^- collisions by BaBar [64], assuming a dark photon, *i.e.*, a Z' boson whose couplings arise only from the kinetic mixing with the hypercharge gauge boson.

In some models, the lower limits on $M_{Z'}$ set by low-energy data are above 1 TeV. For example, $M_{Z_\chi} > 1.1$ TeV and $M_{Z_\eta} > 0.43$ TeV assuming that the Higgs sectors consist of electroweak doublets and singlets only [4], while the gauge coupling is fixed by an $SO(10)$ unification condition for $U(1)_\chi$ and $U(1)_\eta$. For more general models, see Refs. [1, 6, 65]. The mass bounds from direct searches at the LHC [22, 23] exceed the electroweak constraints by a factor of three or more for the models mentioned here. This conclusion could change if the collider bounds are weakened by exotic decay channels [66].

Although the LHC data are most constraining for many Z' models, one should be careful in assessing the relative reach of various experiments given the freedom in Z' couplings. For example, a Z' coupled to $B-yL_\mu+(y-3)L_\tau$ has implications for the muon $g-2$, neutrino oscillations or τ decays, and would be hard to see in processes involving first-generation fermions. Moreover, the combination of LHC searches and low-energy measurements could allow a precise determination of the Z' parameters [67].

88. Supersymmetry, Part I (Theory)

Revised August 2021 by B.C. Allanach (DAMTP, Cambridge U.) and H.E. Haber (UC Santa Cruz).

88.1 Introduction

Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa [1]. The existence of such a non-trivial extension of the Poincaré symmetry of ordinary quantum field theory was initially surprising, and its form is highly constrained by theoretical principles [2]. SUSY also provides a framework for the unification of particle physics and gravity [3–6] at the Planck energy scale, $M_{\rm P} \sim 10^{19}$ GeV, where the gravitational interactions become comparable in strength to the gauge interactions. Moreover, supersymmetry can stabilize the hierarchy between the energy scale that characterizes electroweak symmetry breaking, $M_{\rm EW} \sim 100$ GeV, and the Planck scale [7–10] against large radiative corrections. The stability of this large gauge hierarchy with respect to radiative quantum corrections is not possible to maintain in the Standard Model (SM) without an unnatural fine-tuning of the parameters of the fundamental theory at the Planck scale. In contrast, in a supersymmetric extension of the SM, it is possible to maintain the gauge hierarchy while providing a natural framework for elementary scalar fields.

If supersymmetry were an exact symmetry of nature, then particles and their superpartners, which differ in spin by half a unit, would be degenerate in mass. Since superpartners have not (yet) been observed, supersymmetry must be a broken symmetry. Nevertheless, the stability of the gauge hierarchy can still be maintained if the SUSY breaking is soft [11,12], and the corresponding SUSY-breaking mass parameters are no larger than a few TeV. Whether this is still plausible in light of recent SUSY searches at the LHC (see Sec. 89) will be discussed in Sec. 88.7.

In particular, soft-SUSY-breaking terms of the Lagrangian involve combinations of fields with total mass dimension of three or less, with some restrictions on the dimension-three terms as elucidated in Ref. [11]. The impact of the soft terms becomes negligible at energy scales much larger than the size of the SUSY-breaking masses. Thus, a theory of weak-scale supersymmetry, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry breaking, provides a natural framework for the origin and the stability of the gauge hierarchy [7–10].

At present, there is no unambiguous experimental evidence for the breakdown of the SM at or below the TeV scale. The expectations for new TeV-scale physics beyond the SM are based primarily on three theoretical arguments. First, in a theory with an elementary scalar field of mass m and interaction strength λ (e.g., a quartic scalar self-coupling, the square of a gauge coupling or the square of a Yukawa coupling), the stability with respect to quantum corrections requires the existence of an energy cutoff roughly of order $(16\pi^2/\lambda)^{1/2}m$, beyond which new physics must enter [13]. A significantly larger energy cutoff would require an unnatural fine-tuning of parameters that govern the effective low-energy theory. Applying this argument to the SM leads to an expectation of new physics at the TeV scale [10].

Second, the unification of the three SM gauge couplings at a very high energy close to the Planck scale is possible if new physics beyond the SM (which modifies the running of the gauge couplings above the electroweak scale) is present. The minimal supersymmetric extension of the SM, where superpartner masses lie below a few TeV, provides an example of successful gauge coupling unification [14].

Third, the existence of dark matter that makes up approximately one quarter of the energy density of the universe, cannot be explained within the SM of particle physics [15]. Remarkably, a stable weakly-interacting massive particle (WIMP) whose mass and interaction rate are governed by new physics associated with the TeV-scale can be consistent with the observed density of dark matter (this is the so-called WIMP miracle, which is reviewed in Ref. [16]). The lightest supersymmetric particle, if stable, is a promising (although not the unique) candidate for the dark matter [17–21]. Further aspects of dark matter can be found in Sec. 27.

88.2 Structure of the MSSM

The minimal supersymmetric extension of the SM (MSSM) consists of the fields of the two-Higgs-doublet extension of the SM and the corresponding superpartners [22, 23]. A particle and its superpartner together form a supermultiplet. The corresponding field content of the supermultiplets of the MSSM and their gauge quantum numbers are shown in Table 88.1. The electric charge $Q = T_3 + \frac{1}{2}Y$ is determined in terms of the third component of the weak isospin (T_3) and the U(1) weak hypercharge (Y).

The gauge supermultiplets consist of the gluons and their gluino fermionic superpartners and the SU(2)×U(1) gauge bosons and their gaugino fermionic superpartners. The matter supermultiplets consist of three generations of left-handed quarks and leptons and their scalar superpartners (squarks and sleptons, collectively referred to as sfermions), and the corresponding antiparticles. The Higgs supermultiplets consist of two complex Higgs doublets, their higgsino fermionic superpartners, and the corresponding antiparticles. The enlarged Higgs sector of the MSSM constitutes the minimal structure needed to guarantee the cancellation of gauge anomalies [25] generated by the higgsino superpartners that can appear as internal lines in triangle diagrams with three external electroweak gauge bosons. Moreover, without a second Higgs doublet, one cannot generate mass for both "up"-type and "down"-type quarks (and charged leptons) in a way consistent with the underlying SUSY [26–28].

In the most elegant treatment of SUSY, spacetime is extended to superspace which consistsof the spacetime coordinates and new anticommuting fermionic coordinates θ and $\theta^\dagger$ [29, 30]. Each supermultiplet is represented by a superfield that is a function of the superspace coordinates. The fields of a given supermultiplet (which are functions of the spacetime coordinates) are coefficients of the θ and $\theta^\dagger$ expansion of the corresponding superfield.

Vector superfields contain the gauge-boson fields and their gaugino partners. Chiral superfields contain the spin-0 and spin-

Table 88.1: The fields of the MSSM and their SU(3)×SU(2)×U(1) quantum numbers are listed. For simplicity, only one generation of quarks and leptons is exhibited. For each lepton, quark, and Higgs supermultiplet (each denoted by a hatted upper-case letter), there is a corresponding antiparticle multiplet of charge-conjugated fermions and their associated scalar partners [24].

Field Content of the MSSM						
Super-multiplets	Super-field	Bosonic fields	Fermionic partners	SU(3)	SU(2)	U(1)
gluon/gluino	$\hat{V}_8$	g	$\widetilde{g}$	8	1	0
gauge boson/ gaugino	$\hat{V}$	$W^\pm$, W^0	$\widetilde{W}^\pm$, $\widetilde{W}^0$	1	3	0
	$\hat{V}'$	B	$\widetilde{B}$	1	1	0
slepton/ lepton	$\hat{L}$	$(\widetilde{\nu}_L, \widetilde{e}^-_L)$	$(\nu, e^-)_L$	1	2	-1
	$\hat{E}^c$	$\widetilde{e}^+_R$	e^c_L	1	1	2
squark/ quark	$\hat{Q}$	$(\widetilde{u}_L, \widetilde{d}_L)$	$(u, d)_L$	3	2	1/3
	$\hat{U}^c$	$\widetilde{u}^*_R$	u^c_L	$\bar{3}$	1	$-4/3$
	$\hat{D}^c$	$\widetilde{d}^*_R$	d^c_L	$\bar{3}$	1	2/3
Higgs boson/ higgsino	$\hat{H}_d$	(H^0_d, H^-_d)	$(\widetilde{H}^0_d, \widetilde{H}^-_d)$	1	2	-1
	$\hat{H}_u$	(H^+_u, H^0_u)	$(\widetilde{H}^+_u, \widetilde{H}^0_u)$	1	2	1

1/2 fields of the matter or Higgs supermultiplets. A general supersymmetric Lagrangian is determined by three functions of the chiral superfields [4]: the superpotential, the Kähler potential, and the gauge kinetic function (which can be appropriately generalized to accommodate higher derivative terms [31]). Minimal forms for the Kähler potential and gauge kinetic function, which generate canonical kinetic energy terms for all the fields, are required for renormalizable globally supersymmetric theories. A renormalizable superpotential, which is at most cubic in the chiral superfields, yields supersymmetric Yukawa couplings and mass terms. A combination of gauge invariance and SUSY produces couplings of gaugino fields to matter (or Higgs) fields and their corresponding superpartners. The (renormalizable) MSSM Lagrangian is then constructed by including all possible supersymmetric interaction terms (of dimension four or less) that satisfy SU(3)×SU(2)×U(1) gauge invariance and B–L conservation (where B = baryon number and L = lepton number). Finally, the most general soft-supersymmetry-breaking terms consistent with these symmetries are added [11, 12, 32].

Although the MSSM is the focus of much of this review, there is some motivation for considering non-minimal supersymmetric extensions of the SM. For example, extra structure is needed to generate non-zero neutrino masses as discussed in Sec. 88.8. In addition, in order to address some theoretical issues and tensions associated with the MSSM, it has been fruitful to introduce one additional singlet Higgs superfield. The resulting next-to-minimal supersymmetric extension of the Standard Model (NMSSM) [33] is considered further in Sec. 88.4–88.7 and 88.9. Finally, one is always free to add additional fields to the SM along with the corresponding superpartners. However, only certain choices for the new fields (*e.g.*, the addition of complete SU(5) multiplets) will preserve the successful gauge coupling unification of the MSSM. Some examples will be briefly mentioned in Sec. 88.9.

88.2.1 *R-parity and the lightest supersymmetric particle*

The (renormalizable) SM Lagrangian possesses an accidental global B–L symmetry due to the fact that B and L-violating operators composed of SM fields must have dimension $d = 5$ or larger [34]. Consequently, B and L-violating effects are suppressed by $(M_{\rm EW}/M)^{d-4}$, where M is the characteristic mass scale of the physics that generates the corresponding higher dimensional operators. Indeed, values of M of order the grand unification scale or larger may be responsible for the observed (approximate) stability of the proton and suppression of neutrino masses. Unfortunately, these results are not guaranteed in a generic supersymmetric extension of the SM. For example, it is possible to construct gauge invariant supersymmetric dimension-four B and L-violating operators made up of fields of SM particles and their superpartners. Such operators, if simultaneously present in the theory, could yield a proton decay rate many orders of magnitude larger than the current experimental bound. It is for this reason that B–L conservation is *imposed* on the supersymmetric Lagrangian when defining the MSSM, which is sufficient for eliminating all B and L-violating operators of dimension $d \leq 4$.

As a consequence of the B–L symmetry, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [35]. This implies that all the particles of the SM have even R-parity, whereas the corresponding superpartners have odd R-parity. The conservation of R-parity in scattering and decay processes has a critical impact on supersymmetric phenomenology. For example, any initial state in a scattering experiment will involve ordinary (R-even) particles. Consequently, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. Moreover, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle. In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [19]. Consequently, the LSP in an R-parity-conserving (RPC) theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) momentum, due to the escape of the LSP. Moreover, as noted in Sec. 88.1 and reviewed in Refs. [20] and [21], the stability of the LSP in R-parity-conserving SUSY makes it a promising candidate for dark matter.

The possibility of relaxing the R-parity invariance of the MSSM (which would generate new B and/or L-violating interactions) will be addressed in Sec. 88.8.2. However, note that in R-parity violating (RPV) models, the LSP is no longer stable and thus would not be a viable candidate for the dark matter (unless its lifetime was significantly longer than the age of the universe). In such scenarios, one has to look elsewhere to explain the origin of dark matter.

88.2.2 *The goldstino and gravitino*

In the MSSM, SUSY breaking is accomplished by including the most general renormalizable soft-SUSY-breaking terms consistent with the SU(3)×SU(2)×U(1) gauge symmetry and R-parity invariance. These terms parameterize our ignorance of the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the goldstino ($\widetilde{G}_{1/2}$) must exist. The goldstino would then be the LSP, and could play an important role in supersymmetric phenomenology [36].

However, the goldstino degrees of freedom are physical only in models of spontaneously-broken global SUSY. If SUSY is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergravity [5, 37]. In models of spontaneously-

broken supergravity, the goldstino is "absorbed" by the gravitino ($\widetilde{G}$), the spin-3/2 superpartner of the graviton, via the super-Higgs mechanism [38]. Consequently, the goldstino is removed from the physical spectrum and the gravitino acquires a mass (denoted by $m_{3/2}$). If $m_{3/2}$ is smaller than the mass of the lightest superpartner of the SM particles, then the gravitino is the LSP.

In processes with center-of-mass energy $E \gg m_{3/2}$, one can employ the goldstino–gravitino equivalence theorem [39], which implies that the interactions of the helicity $\pm\frac{1}{2}$ gravitino (whose properties approximate those of the goldstino) dominate those of the helicity $\pm\frac{3}{2}$ gravitino. The interactions of gravitinos with other light fields can be described by a low-energy effective Lagrangian that is determined by fundamental principles [40].

88.2.3 *Hidden sectors and the structure of SUSY breaking*

It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken weak-scale supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. A more successful scheme posits a theory with at least two distinct sectors: a visible sector consisting of the particles of the MSSM [32] and a sector where SUSY breaking is generated. It is often (but not always) assumed that particles of the hidden sector are neutral with respect to the SM gauge group. The effects of the hidden sector supersymmetry breaking are then transmitted to the MSSM by some mechanism (often involving the mediation by particles that comprise an additional messenger sector). Two theoretical scenarios that exhibit this structure are gravity-mediated and gauge-mediated SUSY breaking.

Supergravity models provide a natural mechanism for transmitting the SUSY breaking of the hidden sector to the particle spectrum of the MSSM. In models of gravity-mediated supersymmetry breaking, gravity is the messenger of supersymmetry breaking [41–45]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (*i.e.* suppressed by inverse powers of the Planck mass). The soft-SUSY-breaking parameters with dimensions of mass arise as model-dependent multiples of the gravitino mass $m_{3/2}$. In this scenario, $m_{3/2}$ is of order the electroweak-symmetry-breaking scale, while the gravitino couplings are roughly gravitational in strength [3, 46].[1]

Under certain theoretical assumptions that govern the structure of the Kähler potential (the so-called sequestered form introduced in Ref. [48]), SUSY breaking is due entirely to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [48]. In particular, gaugino masses are radiatively generated at one-loop, and squark and slepton squared-mass matrices are flavor-diagonal. In sequestered scenarios, sfermion squared-masses arise at two-loops, which implies that gluino and sfermion masses are of the same order of magnitude. This approach is called anomaly-mediated SUSY breaking (AMSB). Indeed, anomaly mediation is more generic than originally conceived, and provides a ubiquitous source of SUSY breaking [49]. However in the simplest formulation of AMSB as applied to the MSSM, the squared-masses of the sleptons are negative (known as the tachyonic slepton problem). It may be possible to cure this otherwise fatal flaw in non-minimal extensions of the MSSM [50]. Alternatively, one can assert that anomaly mediation is not the sole source of SUSY breaking in the sfermion sector. In non-sequestered scenarios, sfermion squared-masses can arise at tree-level, in which case squark masses would be parametrically larger than the loop-suppressed gaugino masses [51].

In gauge-mediated supersymmetry breaking (GMSB), gauge forces transmit the supersymmetry breaking to the MSSM. A typical structure of such models involves a hidden sector where SUSY is broken, a messenger sector consisting of particles (messengers) with nontrivial SU(3)×SU(2)×U(1) quantum numbers, and the visible sector consisting of the fields of the MSSM [52–55]. The direct coupling of the messengers to the hidden sector generates a supersymmetry-breaking spectrum in the messenger sector. Supersymmetry breaking is then transmitted to the MSSM via the virtual exchange of the messenger fields. In models of direct gauge mediation, there is no separate hidden sector. In particular, the sector in which the SUSY breaking originates includes fields that carry nontrivial SM quantum numbers, which allows for the direct transmission of SUSY breaking to the MSSM [56].

In models of gauge-mediated SUSY breaking with a minimal Kähler potential, the gravitino is the LSP [17], as its mass can range from a few eV (in the case of low SUSY breaking scales) up to a few GeV (in the case of high SUSY breaking scales). In particular, the gravitino is a potential dark matter candidate (for a review and guide to the literature, see Ref. [21]). The couplings of the helicity $\pm\frac{1}{2}$ components of $\widetilde{G}$ to the particles of the MSSM (which approximate those of the goldstino as previously noted in Sec. 88.2.2) are significantly stronger than gravitational strength and amenable to experimental collider analyses.

The mass ranges of the gravitino in either gravity-mediated or gauge-mediated SUSY breaking are further constrained by cosmological considerations [57, 58]. In particular, there is a danger of over-abundance of gravitinos if it is the dark matter or, if it decays before nucleosynthesis, modifications to the successful predictions of light element abundances. Avoiding these cosmological gravitino problems impose strong constraints on gravity-mediated and gauge-mediated SUSY breaking models.

The concept of a hidden sector is more general than SUSY. Hidden valley models [59] posit the existence of a hidden sector of new particles and interactions that are very weakly coupled to particles of the SM. The impact of a hidden valley on supersymmetric phenomenology at colliders can be significant if the LSP lies in the hidden sector [60].

88.2.4 *SUSY and extra dimensions*

Approaches to SUSY breaking have also been developed in the context of theories in which the number of spatial dimensions is greater than three. In particular, a number of SUSY-breaking mechanisms have been proposed that are inherently extra-dimensional [61]. The size of the extra dimensions can be significantly larger than $M_{\rm P}^{-1}$; in some cases of order $(\text{TeV})^{-1}$ or even larger (see, *e.g.*, Sec. 85 or Ref. [62]).

For example, in one approach the fields of the MSSM live on some brane (a lower-dimensional manifold embedded in a higher-dimensional spacetime), while the sector of the theory that breaks SUSY lives on a second spatially-separated brane. Two examples of this approach are AMSB [48] and gaugino-mediated SUSY breaking [63]. In both cases, SUSY breaking is transmitted through fields that live in the bulk (the higher-dimensional space between the two branes). This setup has some features in common with both gravity-mediated and gauge-mediated SUSY breaking (*e.g.*, hidden and visible sectors and messengers).

Since a higher dimensional theory must be compactified to four spacetime dimensions, one can also generate a source of SUSY breaking by employing boundary conditions on the compactified space that distinguish between fermions and bosons. This is the so-called Scherk-Schwarz mechanism [64]. The phenomenology of such models can be strikingly different from that of the usual MSSM [65].

88.2.5 *Split-SUSY*

If SUSY is not connected with the origin of the electroweak scale, it may still be possible that some remnant of the superparticle spectrum survives down to the TeV-scale or below. This is the idea of split-SUSY [66,67], in which scalar superpartners of the quarks and leptons are significantly heavier than 1 TeV, whereas the fermionic superpartners of the gauge and Higgs bosons have masses on the order of 1 TeV or below. With the exception of a single light neutral scalar whose properties are practically indistinguishable from those of the SM Higgs boson, all other Higgs bosons are also assumed to be very heavy. Among the supersymmetric particles, only the fermionic superpartners may be kinematically accessible at the LHC.

In models of split SUSY, the top squark masses cannot be arbitrarily large, as these parameters enter in the radiative corrections to the mass of the observed Higgs boson [68, 69]. In the MSSM, a Higgs boson mass of 125 GeV (see Sec. 11) implies an upper bound on the top squark mass scale in the range of 10 to 10^8 TeV [70–72],

[1] However, such a gravitino typically plays no direct role in supersymmetric phenomenology at colliders (except perhaps indirectly in the case where the gravitino is the LSP [47]).

depending on the value of the ratio of the two neutral Higgs field vacuum expectation values, although this mass range can be somewhat extended by varying other relevant MSSM parameters. In some approaches, gaugino masses are one-loop suppressed relative to the sfermion masses, corresponding to the so-called mini-split SUSY spectrum [69,73]. The higgsino mass scale may or may not be likewise suppressed depending on the details of the model [74].

The SUSY breaking required to produce such a split-SUSY spectrum would destabilize the gauge hierarchy, and thus would not provide an explanation for the scale of electroweak symmetry breaking. Nevertheless, models of split-SUSY can account for the dark matter (which is assumed to be the LSP gaugino or higgsino) and gauge coupling unification, thereby preserving two of the desirable features of weak-scale SUSY. Finally, as a consequence of the very large squark and slepton masses, neutral flavor changing and CP-violating effects, which can be problematic in models with TeV-scale SUSY-breaking masses, are sufficiently reduced to avoid conflict with experimental observations.

88.3 Parameters of the MSSM

The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving and the supersymmetry-breaking sectors. A careful discussion of the conventions used here in defining the tree-level MSSM parameters can be found in Refs. [75,76]. For simplicity, consider first the case of one generation of quarks, leptons, and their scalar superpartners.

88.3.1 *The SUSY-conserving parameters*

The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings, g_s, g, and g', corresponding to the SM gauge group SU(3)×SU(2)×U(1) respectively; (ii) a supersymmetry-conserving higgsino mass parameter μ; and (iii) Higgs-fermion Yukawa couplings, λ_u, λ_d, and λ_e, of one generation of left- and right-handed quarks and leptons, and their superpartners to the Higgs bosons and higgsinos. Because there is no right-handed neutrino/sneutrino in the MSSM as defined here, a Yukawa coupling λ_ν is not included. The complex μ parameter and Yukawa couplings enter via the most general renormalizable R-parity-conserving superpotential,

$$W_{\rm MSSM} = \lambda_d \hat{H}_d \hat{Q} \hat{D}^c - \lambda_u \hat{H}_u \hat{Q} \hat{U}^c + \lambda_e \hat{H}_d \hat{L} \hat{E}^c + \mu \hat{H}_u \hat{H}_d \,, \quad (88.1)$$

where the superfields are defined in Table 1 and the gauge group indices are suppressed.

88.3.2 *The SUSY-breaking parameters*

The supersymmetry-breaking sector contains the following sets of parameters: (i) three complex gaugino Majorana mass parameters, M_3, M_2, and M_1, associated with the SU(3), SU(2), and U(1) subgroups of the SM; (ii) five sfermion squared-mass parameters, $M^2_{\underset{\sim}{Q}}$, $M^2_{\underset{\sim}{U}}$, $M^2_{\underset{\sim}{D}}$, $M^2_{\underset{\sim}{L}}$, and $M^2_{\underset{\sim}{E}}$, corresponding to the five electroweak gauge multiplets, *i.e.*, superpartners of the left-handed fields $(u,d)_L$, u^c_L, d^c_L, $(\nu,\, e^-)_L$, and e^c_L, where the superscript c indicates a charge-conjugated fermion field [24]; and (iii) three Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with complex coefficients $T_U \equiv \lambda_u A_U$, $T_D \equiv \lambda_d A_D$, and $T_E \equiv \lambda_e A_E$ (which define the "A-parameters"), following the notation employed in Ref. [76]. It is conventional to separate out the factors of the Yukawa couplings in defining the A-parameters (originally motivated by a simple class of gravity-mediated SUSY-breaking models [3,6]). If the A-parameters are parametrically of the same order (or smaller) relative to other SUSY-breaking mass parameters, then in most cases only the third generation A-parameters are phenomenologically relevant.

Finally, we have (iv) two real squared-mass parameters, $m^2_{H_d}$ and $m^2_{H_u}$ (also called m^2_1 and m^2_2, respectively, in the literature), and one complex squared-mass parameter, $m^2_{12} \equiv \mu B$ (the latter defines the "B-parameter"), which appear in the MSSM tree-level scalar Higgs potential [28],

$$\begin{aligned} V = {} & (m^2_{H_d} + |\mu|^2) H^\dagger_d H_d + (m^2_{H_u} + |\mu|^2) H^\dagger_u H_u \\ & + (m^2_{12} H_u H_d + \text{h.c.}) \\ & + \frac{1}{8}(g^2 + g'^2)(H^\dagger_d H_d - H^\dagger_u H_u)^2 + \frac{1}{2} g^2 |H^\dagger_d H_u|^2 \,, \end{aligned} \quad (88.2)$$

where the SU(2)-invariant combination, $H_u H_d \equiv H^+_u H^-_d - H^0_u H^0_d$. Note that the quartic Higgs couplings are related to the gauge couplings g and g' as a consequence of SUSY. The breaking of the SU(2)×U(1) electroweak symmetry group to $\mathrm{U}(1)_{\rm EM}$ is only possible after incorporating the SUSY-breaking Higgs squared-mass parameters $m^2_{H_d}$, $m^2_{H_u}$ (which can be negative) and m^2_{12}. After minimizing the Higgs scalar potential, these three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, $\langle H^0_d \rangle \equiv v_d/\sqrt{2}$ and $\langle H^0_u \rangle \equiv v_u/\sqrt{2}$, and the CP-odd Higgs mass m_A [cf. Eqs. (88.4) and (88.5) below]. One is always free to rephase the Higgs doublet fields such that v_d and v_u (also called v_1 and v_2, respectively, in the literature) are both real and positive.

The quantity, $v^2_d + v^2_u = 4m^2_W/g^2 = (2G^2_F)^{-1/2} \simeq (246\ \text{GeV})^2$, is fixed by the Fermi constant, G_F, whereas the ratio

$$\tan\beta = v_u/v_d \quad (88.3)$$

is a free parameter such that $0 < \beta < \pi/2$. By employing the tree-level conditions resulting from the minimization of the scalar potential, one can eliminate the diagonal and off-diagonal Higgs squared-masses in favor of $m^2_Z = \frac{1}{4}(g^2+g'^2)(v^2_d+v^2_u)$, the CP-odd Higgs mass m_A and the parameter $\tan\beta$,

$$\sin 2\beta = \frac{2m^2_{12}}{m^2_{H_d} + m^2_{H_u} + 2|\mu|^2} = \frac{2m^2_{12}}{m^2_A} \,, \quad (88.4)$$

$$\frac{1}{2} m^2_Z = -|\mu|^2 + \frac{m^2_{H_d} - m^2_{H_u} \tan^2\beta}{\tan^2\beta - 1} \,. \quad (88.5)$$

One must also guard against the existence of charge and/or color breaking global minima due to non-zero vacuum expectation values for the squark and charged slepton fields. This possibility can be avoided if the A-parameters are not unduly large [42,77,78]. Additional constraints must also be respected to avoid the possibility of directions in scalar field space in which the full tree-level scalar potential can become unbounded from below [78]. A computer program has been developed to calculate vacuum stability bounds in general models at the one-loop level [79], and has been applied to the MSSM in Ref. [80].

Note that SUSY-breaking mass terms for the fermionic superpartners of scalar fields and non-holomorphic trilinear scalar interactions (*i.e.*, interactions that mix scalar fields and their complex conjugates) have not been included above in the soft-SUSY-breaking sector. These terms can potentially destabilize the gauge hierarchy [11] in models with a gauge-singlet superfield. The latter is not present in the MSSM; hence as noted in Ref. [12], these so-called non-standard soft-SUSY-breaking terms are benign. The phenomenological impact of non-holomorphic soft SUSY-breaking terms has been reconsidered in Refs. [81–83]. However, in the most common approaches to constructing a fundamental theory of SUSY-breaking, the coefficients of these terms (which have dimensions of mass) are significantly suppressed compared to the TeV-scale [84]. Consequently, we follow the usual approach and omit these terms from further consideration.

88.3.3 *MSSM-124*

The total number of independent physical parameters that define the MSSM (in its most general form) is quite large, primarily due to the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, $M^2_{\underset{\sim}{Q}}$, $M^2_{\underset{\sim}{U}}$, $M^2_{\underset{\sim}{D}}$, $M^2_{\underset{\sim}{L}}$, and $M^2_{\underset{\sim}{E}}$ are hermitian 3×3 matrices, and A_U, A_D, and A_E are complex 3×3 matrices. In addition, M_1, M_2, M_3, B, and μ are in general complex parameters. Finally, as in the SM, the Higgs-fermion Yukawa couplings, λ_f ($f = u$, d, and e), are complex 3×3 matrices that are related to the quark and lepton mass matrices via: $M_f = \lambda_f v_f/\sqrt{2}$, where $v_e = v_d$ [with v_u and v_d as defined above Eq. (88.3)].

However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. [85] shows that the MSSM possesses 124 independent real degrees of freedom. Of these, 18

correspond to SM parameters (including the QCD vacuum angle $\theta_{\rm QCD}$), one corresponds to a Higgs sector parameter (the analogue of the SM Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three CP-violating phases in the gaugino/higgsino sector, 21 squark and slepton (sfermion) masses, 36 real mixing angles to define the sfermion mass eigenstates, and 40 CP-violating phases that can appear in sfermion interactions. The most general parameterization of the R-parity-conserving MSSM (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [86].

88.4 The supersymmetric-particle spectrum

The supersymmetric particles (sparticles) differ in spin by half a unit from their SM partners. The superpartners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" to the end of the corresponding SM particle name. The gluino is the color-octet Majorana fermion partner of the gluon with mass $M_{\widetilde{g}} = |M_3|$. The superpartners of the electroweak gauge and Higgs bosons (the gauginos and higgsinos) can mix due to SU(2)×U(1) breaking effects. As a result, the physical states of definite mass are parameter dependent linear combinations of the charged or neutral gauginos and higgsinos, called charginos and neutralinos, respectively (sometimes collectively called electroweakinos). The neutralinos are Majorana fermions, which can lead to some distinctive phenomenological signatures [87,88]. The superpartners of the quarks and leptons are spin-zero bosons: the squarks, charged sleptons, and sneutrinos, respectively. A complete set of Feynman rules for the sparticles of the MSSM can be found in Ref. [89]. The MSSM Feynman rules also are implicitly contained in a number of amplitude generation and Feynman diagram software packages (see *e.g.*, Refs. [90–92]).

It should be noted that all mass formulae quoted below in this Section are tree-level results. Radiative loop corrections will modify these results and must be included in any precision study of supersymmetric phenomenology [93]. Beyond tree level, the definition of the supersymmetric parameters becomes convention-dependent. For example, one can define physical couplings or running couplings, which differ beyond the tree level. This provides a challenge to any effort that attempts to extract supersymmetric parameters from data. The SUSY Les Houches Accord (SLHA) [76,94] has been adopted, which establishes a set of conventions for specifying generic file structures for supersymmetric model specifications and input parameters, supersymmetric mass and coupling spectra, and decay tables. These provide a universal interface between spectrum calculation programs, decay packages, and high energy physics event generators.

88.4.1 *The charginos and neutralinos*

The mixing of the charged gauginos ($\widetilde{W}^\pm$) and charged higgsinos ($\widetilde{H}_u^+$ and $\widetilde{H}_d^-$) is described (at tree-level) by a 2×2 complex mass matrix [95,96],

$$M_C \equiv \begin{pmatrix} M_2 & \frac{1}{\sqrt{2}} g v_u \\ \frac{1}{\sqrt{2}} g v_d & \mu \end{pmatrix} . \tag{88.6}$$

To determine the physical chargino states and their masses, one must perform a singular value decomposition [97,98] of the complex matrix M_C:

$$U^* M_C V^{-1} = \mathrm{diag}(M_{\tilde{\chi}_1^+}\,,\, M_{\tilde{\chi}_2^+})\,, \tag{88.7}$$

where U and V are unitary matrices, and the right-hand side of Eq. (88.7) is the diagonal matrix of (real non-negative) chargino masses. Explicit formulae for the singular value decomposition of M_C can be found in Ref. [99]. The physical chargino states are denoted by $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^\pm$. These are linear combinations of the charged gaugino and higgsino states determined by the matrix elements of U and V [95,96] The chargino masses correspond to the singular values [97] of M_C, *i.e.*, the positive square roots of the eigenvalues of $M_C^\dagger M_C$:

$$M^2_{\tilde{\chi}_1^+,\tilde{\chi}_2^+} = \frac{1}{2}\Big\{ |\mu|^2 + |M_2|^2 + 2m_W^2 \mp \sqrt{\left(|\mu|^2 + |M_2|^2 + 2m_W^2\right)^2 - 4|\mu M_2 - m_W^2 \sin 2\beta|^2}\,\Big\}, \tag{88.8}$$

in a convention where v_u and v_d are real and positive, and where the states are ordered such that $M_{\tilde{\chi}_1^+} \le M_{\tilde{\chi}_2^+}$. The relative phase of μ^* and M_2 is physical and potentially observable [100].

The mixing of the neutral gauginos ($\widetilde{B}$ and $\widetilde{W}^0$) and neutral higgsinos ($\widetilde{H}_d^0$ and $\widetilde{H}_u^0$) is described (at tree-level) by a 4×4 complex symmetric mass matrix [95,96],

$$M_N \equiv \begin{pmatrix} M_1 & 0 & -\frac{1}{2}g' v_d & \frac{1}{2}g' v_u \\ 0 & M_2 & \frac{1}{2} g v_d & -\frac{1}{2} g v_u \\ -\frac{1}{2}g' v_d & \frac{1}{2} g v_d & 0 & -\mu \\ \frac{1}{2}g' v_u & -\frac{1}{2} g v_u & -\mu & 0 \end{pmatrix} . \tag{88.9}$$

To determine the physical neutralino states and their masses, one must perform an Autonne-Takagi factorization [97,101] (also called Takagi diagonalization [98,102]) of the complex symmetric matrix M_N:

$$W^T M_N W = \mathrm{diag}(M_{\tilde{\chi}_1^0}\,,\, M_{\tilde{\chi}_2^0}\,,\, M_{\tilde{\chi}_3^0}\,,\, M_{\tilde{\chi}_4^0})\,, \tag{88.10}$$

where W is a unitary matrix (which is called N^{-1} in Ref. [95]) and the right-hand side of Eq. (88.10) is the diagonal matrix of (real non-negative) neutralino masses. The physical neutralino states are denoted by $\widetilde{\chi}_i^0$ (for $i = 1,\ldots,4$), where the states are ordered such that $M_{\tilde{\chi}_1^0} \le M_{\tilde{\chi}_2^0} \le M_{\tilde{\chi}_3^0} \le M_{\tilde{\chi}_4^0}$. The $\widetilde{\chi}_i^0$ are the linear combinations of the neutral gaugino and higgsino states determined by the matrix elements of W. The neutralino masses correspond to the singular values of M_N, *i.e.*, the positive square roots of the eigenvalues of $M_N^\dagger M_N$. Exact formulae for these masses can be found in Refs. [103] and [104]. A numerical algorithm for determining the mixing matrix W has been given in Ref. [105].

If a chargino or neutralino state approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if $|M_1|$ and $|M_2|$ are small compared to m_Z and $|\mu|$, then the lightest neutralino $\widetilde{\chi}_1^0$ would be nearly a pure photino, $\widetilde{\gamma}$, the superpartner of the photon. If $|M_1|$ and m_Z are small compared to $|M_2|$ and $|\mu|$, then the lightest neutralino would be nearly a pure bino, $\widetilde{B}$, the superpartner of the weak hypercharge gauge boson. If $|M_2|$ and m_Z are small compared to $|M_1|$ and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure winos, $\widetilde{W}^\pm$, and $\widetilde{W}_3^0$, the superpartners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and m_Z are small compared to $|M_1|$ and $|M_2|$, then the lightest chargino pair and neutralino would be nearly pure higgsino states, the superpartners of the Higgs bosons. Each of the above cases leads to a strikingly different phenomenology.

In the NMSSM, an additional Higgs singlet superfield is added to the MSSM. This superfield comprises two real Higgs scalar degrees of freedom and an associated neutral higgsino degree of freedom. Consequently, there are five neutralino mass eigenstates that are obtained by a Takagi-diagonalization of the 5×5 neutralino mass matrix. In many cases, the fifth neutralino state is dominated by its SU(2)×U(1) singlet component, and thus is very weakly coupled to the SM particles and their superpartners.

88.4.2 *The squarks and sleptons*

For a given Dirac fermion f, there are two superpartners, $\widetilde{f}_L$ and $\widetilde{f}_R$, where the L and R subscripts simply identify the scalar partners that are related by SUSY to the left-handed and right-handed fermions, $f_{L,R} \equiv \frac{1}{2}(1 \mp \gamma_5) f$, respectively. (There is no $\widetilde{\nu}_R$ in the MSSM.) However, $\widetilde{f}_L$–$\widetilde{f}_R$ mixing is possible, in which case $\widetilde{f}_L$ and $\widetilde{f}_R$ are not mass eigenstates. For three generations of squarks, one must diagonalize 6×6 matrices corresponding to the basis $(\widetilde{q}_{iL}, \widetilde{q}_{iR})$, where $i = 1,2,3$ are the generation labels.

For simplicity, only the one-generation case is illustrated in detail below. (The effects of second and third generation squark mixing can be significant and are treated in Ref. [106].)

Using the notation of the third family, the one-generation tree-level squark squared-mass matrix is given by [107],

$$\mathcal{M}^2 = \begin{pmatrix} M^2_{\widetilde{Q}} + m_q^2 + L_q & m_q X_q^* \\ m_q X_q & M^2_{\widetilde{R}} + m_q^2 + R_q \end{pmatrix} , \qquad (88.11)$$

where

$$X_q \equiv A_q - \mu^* (\cot\beta)^{2T_{3q}} , \qquad (88.12)$$

and $T_{3q} = \frac{1}{2}$ $[-\frac{1}{2}]$ for $q = t$ $[b]$. The diagonal squared-masses are governed by soft-SUSY-breaking squared-masses $M^2_{\widetilde{Q}}$ and $M^2_{\widetilde{R}} \equiv M^2_{\widetilde{U}}$ $[M^2_{\widetilde{D}}]$ for $q = t$ $[b]$, the corresponding quark masses m_t $[m_b]$ and the electroweak correction terms:

$$\begin{aligned} L_q &\equiv (T_{3q} - e_q \sin^2\theta_W) m_Z^2 \cos 2\beta , \\ R_q &\equiv e_q \sin^2\theta_W \, m_Z^2 \cos 2\beta , \end{aligned} \qquad (88.13)$$

where $e_q = \frac{2}{3}$ $[-\frac{1}{3}]$ for $q = t$ $[b]$. The off-diagonal squark squared-masses are proportional to the corresponding quark masses and depend on $\tan\beta$, the soft-SUSY-breaking A-parameters and the higgsino mass parameter μ. Assuming that the A-parameters are parametrically of the same order (or smaller) relative to other SUSY-breaking mass parameters, it then follows that the first and second generation $\widetilde{q}_L$–$\widetilde{q}_R$ mixing is smaller than that of the third generation where mixing can be enhanced by factors of m_t and $m_b \tan\beta$.

In the case of third generation $\widetilde{q}_L$–$\widetilde{q}_R$ mixing, the mass eigenstates (usually denoted by $\widetilde{q}_1$ and $\widetilde{q}_2$, with $m_{\tilde{q}_1} < m_{\tilde{q}_2}$) are determined by diagonalizing the 2×2 matrix $\mathcal{M}^2$ given by Eq. (88.11). The corresponding squared-masses and mixing angle are given by [107]:

$$\begin{aligned} m^2_{\tilde{q}_{1,2}} &= \frac{1}{2}\left[\mathrm{Tr}\,\mathcal{M}^2 \mp \sqrt{(\mathrm{Tr}\mathcal{M}^2)^2 - 4\det\mathcal{M}^2} \right] , \\ \sin 2\theta_{\tilde{q}} &= \frac{2 m_q |X_q|}{m^2_{\tilde{q}_2} - m^2_{\tilde{q}_1}} . \end{aligned} \qquad (88.14)$$

The one-generation results above also apply to the charged sleptons, with the obvious substitutions: $q \to \ell$ with $T_{3\ell} = -\frac{1}{2}$ and $e_\ell = -1$, and the replacement of the SUSY-breaking parameters: $M^2_{\widetilde{Q}} \to M^2_{\widetilde{L}}$, $M^2_{\widetilde{D}} \to M^2_{\widetilde{E}}$, and $A_q \to A_\tau$. For the neutral sleptons, $\widetilde{\nu}_R$ does not exist in the MSSM, so $\widetilde{\nu}_L$ is a mass eigenstate.

In the case of three generations, the SUSY-breaking scalar-squared masses [$M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$, and $M^2_{\widetilde{E}}$] and the A-parameters [A_U, A_D, and A_E] are now 3×3 matrices as noted in Sec. 88.3.3. The diagonalization of the 6×6 squark mass matrices yields $\widetilde{f}_{iL}$–$\widetilde{f}_{jR}$ mixing. In practice, since the $\widetilde{f}_L$–$\widetilde{f}_R$ mixing is appreciable only for the third generation, this additional complication can often be neglected (although see Ref. [106] for examples in which the mixing between the second and third generation squarks is relevant).

88.5 The supersymmetric Higgs sector

Consider first the MSSM Higgs sector [27, 28, 108]. Despite the large number of potential CP-violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs potential given by Eq. (88.2) is automatically CP-conserving. This follows from the fact that the only potentially complex parameter (m^2_{12}) of the MSSM Higgs potential can be chosen real and positive by rephasing the Higgs fields, in which case $\tan\beta$ is a real positive parameter. Consequently, the physical neutral Higgs scalars are CP-eigenstates (at tree-level). The MSSM Higgs sector contains five physical spin-zero particles: a charged Higgs boson pair ($H^\pm$), two CP-even neutral Higgs bosons (denoted by h^0 and H^0 where $m_h < m_H$), and one CP-odd neutral Higgs boson (A^0). The discovery of a SM-like Higgs boson at the LHC with a mass of 125 GeV (see Sec. 11) strongly suggests that this state should be identified with h^0, although the possibility that the 125 GeV state should be identified with H^0 cannot yet be completely ruled out [109].

In the NMSSM [33], the scalar component of the singlet Higgs superfield adds two additional neutral states to the Higgs sector. In this model, the tree-level Higgs sector can exhibit explicit CP-violation. If CP is conserved, then the two extra neutral scalar states are CP-even and CP-odd, respectively. These states can potentially mix with the neutral Higgs states of the MSSM. If scalar states exist that are dominantly singlet, then they are weakly coupled to SM gauge bosons and fermions through their small mixing with the MSSM Higgs scalars. Consequently, it is possible that one (or both) of the singlet-dominated states is considerably lighter than the Higgs boson that was observed at the LHC.

88.5.1 *The tree-level Higgs sector*

The tree-level properties of the Higgs sector are determined by the Higgs potential given by Eq. (88.2). The quartic interaction terms are manifestly supersymmetric (although these are modified by SUSY-breaking effects at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called "F-terms"), and (ii) interaction terms related by SUSY to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called "D-terms").

In the MSSM, F-term contributions to the quartic Higgs self-couplings are absent. As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings, as noted below Eq. (88.2). Consequently, all the tree-level MSSM Higgs-sector parameters depend only on two quantities: $\tan\beta$ [defined in Eq. (88.3)] and one Higgs mass usually taken to be m_A. From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle α that measures the mixture of the hypercharge ± 1 scalar fields, H_u^0 and H_d^0, in the physical CP-even neutral scalars, and the Higgs boson self-couplings. Moreover, the tree-level mass of the lighter CP-even Higgs boson is bounded, $m_h \leq m_Z |\cos 2\beta| \leq m_Z$ [27, 28]. This bound can be substantially modified when radiative corrections are included, as discussed in Sec. 88.5.2.

In the NMSSM, we set $\mu = 0$ in Eq. 88.1 and then add two additional terms to the superpotential,

$$W_{\rm NMSSM} \ni \lambda \hat{H}_u \hat{H}_d \hat{S} + \frac{1}{3}\kappa \hat{S}^3 , \qquad (88.15)$$

where $\hat{S}$ is a singlet Higgs superfield. An effective μ term is generated, $\mu_{\rm eff} = \lambda\langle S\rangle$, where $\langle S\rangle$ is the vacuum expectation value of the scalar field component of $\hat{S}$. Moreover, due to the term proportional to λ in Eq. 88.15, there is now an F-term contribution to the quartic Higgs self-couplings. Consequently, the tree-level bound for the mass of the lightest CP-even MSSM Higgs boson is modified [110],

$$m_h^2 \leq m_Z^2 \cos^2 2\beta + \frac{1}{2}\lambda^2 v^2 \sin^2 2\beta , \qquad (88.16)$$

where $v \equiv (v_u^2 + v_d^2)^{1/2} = 246$ GeV. By requiring that λ remain finite after renormalization-group evolution up to the Planck scale, one finds that λ is constrained to lie below about 0.7–0.8 at the electroweak scale [33] (although larger values of λ have also been considered in Ref. [111]).

The tree-level Higgs-quark and Higgs-lepton interactions of the MSSM are governed by the Yukawa couplings defined by the superpotential given in Eq. (88.1). In particular, the Higgs sector of the MSSM is a Type-II two-Higgs doublet model [112], in which one Higgs doublet (H_d) couples exclusively to the right-handed down-type quark (or lepton) fields and the second Higgs doublet (H_u) couples exclusively to the right-handed up-type quark fields. Consequently, the diagonalization of the fermion mass matrices simultaneously diagonalizes the matrix of Yukawa couplings, resulting in flavor-diagonal tree-level couplings of the neutral Higgs bosons h^0, H^0 and A^0 to quark and lepton pairs.

88.5.2 *The radiatively-corrected Higgs sector*

When radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual supersymmetric particles that appear in loops. The impact of these corrections

can be significant [113]. The qualitative behavior of these radiative corrections can be most easily seen in the large top-squark mass limit, where in addition, both the splitting of the two diagonal entries and the off-diagonal entries of the top-squark squared-mass matrix [Eq. (88.11)] are small in comparison to the geometric mean of the two top-squark squared-masses, $M_{\rm S}^2 \equiv M_{\tilde{t}_1} M_{\tilde{t}_2}$. In this case (assuming $\mathrm{m}_A > m_Z$), the predicted upper bound for m_h is approximately given by [114]

$$m_h^2 \lesssim m_Z^2 \cos^2 2\beta + \frac{3g^2 m_t^4}{8\pi^2 m_W^2}\left[\ln\left(\frac{M_{\rm S}^2}{m_t^2}\right) + \frac{X_t^2}{M_{\rm S}^2}\left(1 - \frac{X_t^2}{12 M_{\rm S}^2}\right)\right], \tag{88.17}$$

where $X_t \equiv A_t - \mu\cot\beta$ [cf. Eq. (88.12)] is proportional to the off-diagonal entry of the top-squark squared-mass matrix (where for simplicity, A_t and μ are taken to be real). The Higgs mass upper limit specified by Eq. (88.17) is saturated when $\tan\beta$ is large (*i.e.*, $\cos^2 2\beta \sim 1$) and $X_t = \sqrt{6}\, M_S$, which defines the so-called maximal mixing scenario.

A more complete treatment of the radiative corrections shows that Eq. (88.17) somewhat overestimates the true upper bound of m_h. These more refined computations, which incorporate renormalization group improvement, the two loop and the leading three-loop contributions, yield $m_h \lesssim 135$ GeV in the region of large $\tan\beta$ (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 2$ TeV [115, 116].

In addition, one-loop radiative corrections can introduce CP-violating effects in the Higgs sector that depend on some of the CP-violating phases among the MSSM-124 parameters [117]. This phenomenon is most easily understood in a scenario where $m_A \ll M_S$ (i.e., all five physical Higgs states are significantly lighter than the SUSY breaking scale). In this case, one can integrate out the heavy superpartners to obtain a low-energy effective theory with two Higgs doublets. The resulting effective two-Higgs doublet model will now contain all possible Higgs self-interaction terms (both CP-conserving and CP-violating) and Higgs-fermion interactions (beyond those of Type-II) that are consistent with electroweak gauge invariance [118].

In the NMSSM with $m_h \simeq 125$ GeV, the dominant radiative correction to Eq. (88.16) is the same as the one given in Eq. (88.17). However, in contrast to the MSSM, one does not need as large a boost from the radiative corrections to achieve a Higgs mass of 125 GeV in certain regimes of the NMSSM parameter space (*e.g.*, $\tan\beta \sim 2$ and $\lambda \sim 0.7$ [119]).

88.6 Restricting the MSSM parameter freedom

In Sections 88.4 and 88.5, we surveyed the parameters that comprise the MSSM-124. However, the MSSM in its most general form is not a phenomenologically viable theory over much of its parameter space. In particular, a generic point of the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers L_e, L_μ, and L_τ; (ii) unsuppressed flavor-changing neutral currents (FCNCs); and (iii) new sources of CP violation that are inconsistent with the experimental bounds.

For example, the MSSM contains many new sources of CP violation [120]. Indeed, for TeV-scale sfermion and gaugino masses, some combinations of the complex phases of the gaugino-mass parameters, the A-parameters, and μ must be less than about 10^{-2}–10^{-3} to avoid generating electric dipole moments for the neutron, electron, and atoms [121–123] in conflict with observed data [124, 125]. The rarity of FCNCs [126–128] places additional constraints on the off-diagonal matrix elements of the squark and slepton soft-SUSY-breaking squared-masses and A-parameters (see Sec. 88.3.3).

The MSSM-124 is also theoretically incomplete as it provides no explanation for the fundamental origin of the supersymmetry-breaking parameters. The successful unification of the MSSM gauge couplings at a grand unified mass scale $M_{\rm GUT}$, close to the Planck scale [8, 67, 129–131],

$$g_s(M_{\rm GUT}) = g(M_{\rm GUT}) = \sqrt{\frac{5}{3}}\, g'(M_{\rm GUT}), \tag{88.18}$$

suggests that the high-energy structure of the theory may be considerably simpler than its low-energy realization.[2] In a top-down approach, the dynamics that governs the more fundamental theory at high energies is used to derive the effective broken-supersymmetric theory at the TeV scale. A suitable choice for the high energy dynamics is one that yields a TeV-scale theory that satisfies all relevant phenomenological constraints.

In this Section, we examine a number of theoretical frameworks that potentially yield phenomenologically viable regions of the MSSM-124 parameter space. The resulting supersymmetric particle spectrum is then a function of a relatively small number of input parameters. This is accomplished by imposing a simple structure on the soft SUSY-breaking parameters at a common high-energy scale M_X (typically chosen to be the Planck scale, M_P, the grand unified theory scale, $M_{\rm GUT}$, or the messenger scale, $M_{\rm mess}$). These serve as initial conditions for the MSSM renormalization group equations (RGEs), which are given in the two-loop approximation in Ref. [132]. Automated programs to compute RGEs for the MSSM and other supersymmetric models of new physics has been developed in Ref. [133]. Solving these equations numerically, one can then derive the low-energy MSSM parameters relevant for phenomenology. A number of software packages exist that numerically calculate the spectrum of supersymmetric particles, consistent with theoretical conditions on SUSY breaking at high energies and some experimental data at low energies [116, 134].

Examples of viable frameworks are provided by models of gravity-mediated, anomaly mediated and gauge-mediated SUSY breaking, to be discussed in more detail below. In some of these approaches, one of the diagonal Higgs squared-mass parameters is driven negative by renormalization group evolution [135]. In such models, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy SUSY breaking.

88.6.1 *Gaugino mass relations*

One prediction of many supersymmetric grand unified models is the unification of the (tree-level) gaugino mass parameters[3] at some high-energy scale, M_X,

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}\,. \tag{88.19}$$

Due to renormalization group running, in the one-loop approximation the effective low-energy gaugino mass parameters (at the electroweak scale) are related,

$$M_3 = (g_s^2/g^2)M_2 \simeq 3.5 M_2\ , \qquad M_1 = (5g'^2/3g^2)M_2 \simeq 0.5 M_2. \tag{88.20}$$

Eq. (88.20) can arise more generally in gauge-mediated SUSY-breaking models where the gaugino masses are generated at the messenger scale $M_{\rm mess}$ (which typically lies significantly below the unification scale where the gauge couplings unify). In this case, the gaugino mass parameters are proportional to the corresponding squared gauge couplings at the messenger scale.

When Eq. (88.20) is satisfied, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ, and $\tan\beta$. It then follows that the lightest neutralino must be heavier than 46 GeV due to the non-observation of charginos at LEP [137]. If in addition $|\mu| \gg |M_1| \gtrsim m_Z$, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders. Although Eq. (88.20) is often assumed in many phenomenological studies, a truly model-independent approach would take the gaugino mass parameters, M_i, to be independent parameters to be determined by experiment. Indeed, an approximately massless neutralino *cannot* be ruled out at present by a model-independent analysis [138].

[2] Generically, the normalization of the U(1) hypercharges exhibited in Table 88.1 is a matter of convention. In particular, the U(1) hypercharges can be rescaled by absorbing the scaling factor into a redefinition of the hypercharge gauge coupling g'. However, the embedding of the hypercharge U(1) generator into the Lie algebra of a grand unified simple gauge group fixes the normalization of the U(1) hypercharges and results in the rescaled hypercharge gauge coupling shown in Eq. (88.18).

[3] Non-universal gaugino mass parameters can also be a viable option in grand unified models with non-minimal gauge kinetic functions [136].

It is possible that the tree-level masses for the gauginos are zero. In this case, the gaugino mass parameters arise at one-loop and do not satisfy Eq. (88.20). For example, the gaugino masses in AMSB models arise entirely from a model-independent contribution derived from the super-conformal anomaly [48, 139]. In this case, Eq. (88.20) is replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2}\,, \tag{88.21}$$

where $m_{3/2}$ is the gravitino mass and the b_i are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2), and SU(3) gauge groups, $(b_1, b_2, b_3) = (\frac{33}{5}, 1, -3)$. Eq. (88.21) yields $M_1 \simeq 2.8 M_2$ and $M_3 \simeq -8.3 M_2$, which implies that the lightest chargino pair and neutralino comprise a nearly mass-degenerate triplet of winos, $\widetilde{W}^{\pm}$, $\widetilde{W}^0$ (cf. Table 1), over most of the MSSM parameter space. For example, if $|\mu| \gg m_Z, |M_2|$, then Eq. (88.21) implies that $M_{\widetilde{\chi}^{\pm}} \simeq M_{\widetilde{\chi}^0_1} \simeq M_2$ [140]. Alternatively, one can construct an AMSB model where $|\mu|, m_Z \ll M_2$, which yields an LSP that is an approximate higgsino state [141]. In both cases, the corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (88.20) [142, 143].

Finally, it should be noted that the unification of gaugino masses (and scalar masses) can be accidental. In particular, the energy scale where unification takes place may not be directly related to any physical scale. One version of this phenomenon has been called mirage unification and can occur in certain theories of fundamental SUSY breaking [144].

88.6.2 *Constrained versions of the MSSM: mSUGRA, CMSSM, etc.*

In the minimal supergravity (mSUGRA) framework [3–6, 41–43], the minimal form of the Kähler potential is employed, which yields standard kinetic energy terms for the MSSM fields [45]. As a result, the soft supersymmetry-breaking parameters at the high-energy scale M_X take a particularly simple form in which the scalar squared-masses and the A-parameters are flavor-diagonal and universal [43]:

$$\begin{aligned}
&M^2_{\widetilde{Q}}(M_X) = M^2_{\widetilde{U}}(M_X) = M^2_{\widetilde{D}}(M_X) = m_0^2 \mathbf{1}\,,\\
&M^2_{\widetilde{L}}(M_X) = M^2_{\widetilde{E}}(M_X) = m_0^2 \mathbf{1}\,,\\
&m_1^2(M_X) = m_2^2(M_X) = m_0^2\,,\\
&A_U(M_X) = A_D(M_X) = A_E(M_X) = A_0 \mathbf{1}\,,
\end{aligned} \tag{88.22}$$

where $\mathbf{1}$ is a 3×3 identity matrix in generation space. As in the SM, this approach exhibits minimal flavor violation [145, 146], whose unique source is the nontrivial flavor structure of the Higgs-fermion Yukawa couplings. The gaugino masses are also unified according to Eq. (88.19).

Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark masses, one should use the low-energy values for $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, and $M^2_{\widetilde{D}}$ in Eq. (88.11). Through the renormalization group running with boundary conditions specified in Eq. (88.20) and Eq. (88.22), one can show that the low-energy values of $M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, and $M^2_{\widetilde{D}}$ depend primarily on m_0^2 and $m_{1/2}^2$. A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. [147].

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 SM parameters (excluding the Higgs mass), one must specify m_0, $m_{1/2}$, A_0, the Planck-scale values for μ and B-parameters (denoted by μ_0 and B_0), and the gravitino mass $m_{3/2}$. Without additional model assumptions, $m_{3/2}$ is independent of the parameters that govern the mass spectrum of the superpartners of the SM [43]. In principle, A_0, B_0, μ_0, and $m_{3/2}$ can be complex, although in the mSUGRA approach, these parameters are taken to be real for simplicity.

As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The most common procedure is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ [the sign of μ_0, denoted $\mathrm{sgn}(\mu_0)$ below, is not fixed in this process]. In this case, the MSSM spectrum and its interaction strengths are determined by five parameters:

$$m_0\,,\ A_0\,,\ m_{1/2}\,,\ \tan\beta\,,\ \text{and}\ \mathrm{sgn}(\mu_0)\,, \tag{88.23}$$

and an independent gravitino mass $m_{3/2}$ (in addition to the 18 parameters of the SM). In Ref. [148], this framework was dubbed the constrained minimal supersymmetric extension of the SM (CMSSM). Additional relations such as $B_0 = A_0 - m_0$ and $m_{3/2} = m_0$ comprise the original mSUGRA proposal [41, 45, 149].

One can also relax the universality of scalar masses by decoupling the squared-masses of the Higgs bosons and the squarks/sleptons. This leads to the non-universal Higgs mass models (NUHMs), thereby adding one or two new parameters to the CMSSM depending on whether the diagonal Higgs scalar squared-mass parameters ($m^2_{H_d}$ and $m^2_{H_u}$) are set equal (NUHM1 [150]) or taken to be independent (NUHM2 [151]) at the high energy scale M_X. Clearly, this modification preserves the minimal flavor violation of the mSUGRA approach. Nevertheless, the mSUGRA approach and its NUHM generalizations are probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft SUSY-breaking parameters is not generic [152]. In particular, effective operators at the Planck scale exist that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

In the framework of supergravity, if anomaly mediation is the sole source of SUSY breaking, then the gaugino mass parameters, diagonal scalar squared-mass parameters, and the SUSY-breaking trilinear scalar interaction terms (proportional to $\lambda_f A_F$) are determined in terms of the beta functions of the gauge and Yukawa couplings and the anomalous dimensions of the squark and slepton fields [48, 139, 143]. As noted in Sec. 88.2.3, this approach yields tachyonic sleptons in the MSSM unless additional sources of SUSY breaking are present. In the minimal AMSB (mAMSB) scenario, a universal squared-mass parameter, m_0^2, is added to the AMSB expressions for the diagonal scalar squared-masses [143]. Thus, the mAMSB spectrum and its interaction strengths are determined by four parameters, m_0^2, $m_{3/2}$, $\tan\beta$ and $\mathrm{sgn}(\mu_0)$.

The mAMSB scenario appears to be ruled out based on the observed value of the Higgs boson mass, assuming an upper limit on M_S of a few TeV, since the mAMSB constraint on A_F implies that the maximal mixing scenario cannot be achieved [cf. Eq. (88.17)]. Indeed, under the stated assumptions, the mAMSB Higgs mass upper bound lies below the observed Higgs mass value [153]. Thus within the AMSB scenario, either an additional SUSY-breaking contribution to $\lambda_f A_F$ and/or new ingredients beyond the MSSM are required.

88.6.3 *Gauge-mediated SUSY breaking*

In contrast to models of gravity-mediated SUSY breaking, the flavor universality of the fundamental soft SUSY-breaking squark and slepton squared-mass parameters is guaranteed in gauge-mediated SUSY breaking (GMSB) because the supersymmetry breaking is communicated to the sector of MSSM fields via gauge interactions [53, 55]. In GMSB models, the mass scale of the messenger sector (or its equivalent) is sufficiently below the Planck scale such that the additional SUSY-breaking effects mediated by supergravity can be neglected.

In the minimal GMSB approach, there is one effective mass scale, Λ, that determines all low-energy scalar and gaugino mass parameters through loop effects, while the resulting A-parameters are suppressed. In addition, the minimal form of the Kähler potential is employed. In order that the resulting superpartner masses be of order 1 TeV, one must have $\Lambda \sim \mathcal{O}(100\ \text{TeV})$. The origin of the μ and B-parameters is model-dependent, and lies somewhat outside the ansatz of gauge-mediated SUSY breaking [154].

The simplest GMSB models appear to be ruled out based on the

observed value of the Higgs boson mass. Due to suppressed A parameters, it is difficult to boost the contributions of the radiative corrections in Eq. (88.17) to obtain a Higgs mass as large as 125 GeV. However, this conflict can be alleviated in more complicated GMSB models [155]. To analyze these generalized GMSB models, it has been especially fruitful to develop model-independent techniques that encompass all known GMSB models [156]. These techniques are well-suited for a comprehensive analysis [157] of the phenomenological profile of gauge-mediated SUSY breaking.

The gravitino is the LSP in minimal GMSB models, as noted in Sec. 88.2.3. As a result, the next-to-lightest supersymmetric particle (NLSP) now plays a crucial role in the phenomenology of supersymmetric particle production and decays. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\tilde{\chi}_1^0$ and $\widetilde{\tau}_R^{\pm}$. The NLSP will decay into its superpartner plus a gravitino (*e.g.*, $\tilde{\chi}_1^0 \to \gamma\widetilde{G}$, $\tilde{\chi}_1^0 \to Z\widetilde{G}$, $\tilde{\chi}_1^0 \to h^0\widetilde{G}$ or $\widetilde{\tau}_1^{\pm} \to \tau^{\pm}\widetilde{G}$), with lifetimes and branching ratios that depend on the model parameters. There are also GMSB scenarios in which there are several nearly degenerate co-NLSPs, any one of which can be produced at the penultimate step of a supersymmetric decay chain [158]. For example, in the slepton co-NLSP case, all three right-handed sleptons are close enough in mass and thus can each play the role of the NLSP.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [55,159]. For example, a long-lived $\tilde{\chi}_1^0$-NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the standard phenomenology of the $\tilde{\chi}_1^0$-LSP). On the other hand, if $\tilde{\chi}_1^0 \to \gamma\widetilde{G}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly *all* supersymmetric particle decay chains would produce a photon. In contrast, in the case of a $\widetilde{\tau}_1^{\pm}$-NLSP, the $\widetilde{\tau}_1^{\pm}$ would either be long-lived or would decay inside the detector into a τ-lepton plus missing energy.

A number of attempts have been made to address the origins of the μ and B-parameters in GMSB models based on the field content of the MSSM (see, *e.g.*, Refs. [154, 160]). An alternative approach is to consider GMSB models based on the NMSSM [161]. The vacuum expectation value of the additional singlet Higgs superfield can be used to generate effective μ and B-parameters [162]. Such models provide an alternative GMSB framework for achieving a Higgs mass of 125 GeV, while still being consistent with LHC bounds on supersymmetric particle masses.

88.6.4 *The phenomenological MSSM*

Any of the theoretical assumptions described in the previous three subsections must be tested experimentally and could turn out to be wrong. To facilitate the exploration of MSSM phenomena in a more model-independent way while respecting the constraints noted at the beginning of this Section, the phenomenological MSSM (pMSSM) has been introduced [163].

The pMSSM is governed by 19 independent real supersymmetric parameters: the three gaugino mass parameters M_1, M_2 and M_3, the Higgs sector parameters m_A and $\tan\beta$, the Higgsino mass parameter μ, five sfermion squared-mass parameters for the degenerate first and second generations ($M^2_{\widetilde{Q}}$, $M^2_{\widetilde{U}}$, $M^2_{\widetilde{D}}$, $M^2_{\widetilde{L}}$ and $M^2_{\widetilde{E}}$), the five corresponding sfermion squared-mass parameters for the third generation, and three third-generation A-parameters (A_t, A_b and A_τ). The first and second generation A-parameters are typically neglected in pMSSM studies, as their phenomenological consequences are negligible in most applications. One counterexample arises when considering the A_μ dependence of the anomalous magnetic moment of the muon, which can be as significant as other contributions due to superpartner mediated radiative corrections [164]. Since its initial proposal, the pMSSM approach has been extended to include a 20th parameter, A_μ [165]. It also has been further extended to include CP-violating SUSY-breaking parameters in Ref. [166].

The 19-parameter pMSSM is often further constrained to expedite scans over the parameter space. For example, in Ref. [167], the number of pMSSM parameters is reduced to ten by assuming one common squark squared-mass parameter for the first two generations, a second common squark squared-mass parameter for the third generation, a common (charged) slepton squared-mass parameter and a common third generation A parameter. In Ref. [168] an eleven parameter pMSSM is defined by allowing for a different stau squared-mass parameter from that of the first two generation charged sleptons. Other applications of the pMSSM approach (with a reduced pMSSM parameter space) to supersymmetric particle searches, and a discussion of the implications for past and future LHC and dark matter studies can be found in Refs. [167, 169, 170].

88.6.5 *Simplified models*

As Sec. 89 demonstrates, experiments present their searches for supersymmetric particles primarily in terms of simplified models. Simplified models for supersymmetric searches [171] are defined mostly by the empirical objects and kinematic variables involved in the search. Their interpretation by an experimental collaboration usually involves only a small number of supersymmetric particles (often two or three). Other supersymmetric particles are assumed to play no role (this may happen by virtue of them being too heavy to be produced). Experimental bounds from non-observation of a signal are usually presented in terms of the physical masses of the supersymmetric particles involved. Bounds may be presented on the relevant supersymmetric particle masses assuming certain values for the branching ratio of certain supersymmetric particle decays, or as an upper bound on the signal production cross-section as a function of the relevant supersymmetric particle masses.

For example, consider a search for hadronic jets plus missing transverse momentum. One can match such a search to the simplified model of squark pair production followed by the subsequent decay of each squark into a quark (which appears as a jet) and a neutralino LSP that produces the missing transverse momentum, *i.e.* $\tilde{q}\tilde{q} \to (q\tilde{\chi}_1^0)(q\tilde{\chi}_1^0)$. Excluded cross-sections resulting from the non-observation of a signal (which in this case could consist of some specified minimum value of missing transverse momentum and at least two hard jets) may be exhibited in the squark mass versus LSP mass plane.

Simplified models have the advantage that they have fewer free parameters than more complete supersymmetric models, whose greater number of free parameters makes it difficult to present excluded regions in any generality. If limits are quoted on supersymmetric particle masses without reference to the signal production cross-section from a simplified model analysis, then there is a potential pitfall—namely, mass limits can differ from those obtained in full models because there may be contributions to the signal coming from processes involving supersymmetric particles other than those assumed. For example, in the $\tilde{q}\tilde{q} \to q\tilde{\chi}_1^0 q\tilde{\chi}_1^0$ process mentioned above, the simplified model analysis does not account for the interference with tree-level t-channel contributions involving the gluino. Nevertheless, simplified model bounds quoted purely in terms of supersymmetric particle masses may still approximately hold over sizeable regions of parameter space of more complete models, within which the simplified model is embedded. When simplified model limits are phrased as bounds on signal cross-sections, the aforementioned pitfall is sidestepped. Simplified models thus remain an efficient tool for organizing and presenting the results of supersymmetric particle searches. A comparison between supersymmetric particle search constraints in the context of simplified models and the corresponding constraints obtained in the more complete pMSSM can be found in Ref. [172].

88.7 Experimental data confronts the MSSM

At present, there is no significant evidence for weak-scale SUSY from the data analyzed by the LHC experiments. Recent LHC data have been effectively employed in ruling out the existence of colored supersymmetric particles (primarily the gluino and the first generation of squarks) with masses below about 2 TeV (see Fig. 89.13). However, the precise mass limits are very model dependent. For example, as Fig. 89.12 demonstrates, regions of the pMSSM parameter space can be identified in which lighter squarks and gluinos below 1 TeV cannot be definitely ruled out. Under the assumption of gaugino mass unification [cf. Eq. (88.20)],

LHC searches result in a lower bound on neutralino and chargino masses of roughly 200 GeV. It is difficult to place general bounds on neutralino and chargino masses, since the limit in terms of masses from direct searches tends to be particularly model dependent. Nevertheless, one must confront the tension that exists between the theoretical expectations for the magnitude of the SUSY-breaking parameters and the non-observation of supersymmetric phenomena at colliders.

88.7.1 *Naturalness constraints and the little hierarchy*

In Sec. 88.1, weak-scale SUSY was motivated as a natural solution to the hierarchy problem, which could provide an understanding of the origin of the electroweak symmetry-breaking scale without a significant fine-tuning of the fundamental parameters that govern the MSSM. In this context, the weak scale soft supersymmetry-breaking masses must be generally of the order of 1 TeV or below [173]. This requirement is most easily seen in the determination of m_Z by the scalar potential minimum condition. In light of Eq. (88.5), to avoid the fine-tuning of MSSM parameters, the soft SUSY-breaking squared-masses $m^2_{H_d}$ and $m^2_{H_u}$ and the higgsino squared-mass $|\mu|^2$ should all be roughly of $\mathcal{O}(m_Z^2)$. Many authors have proposed quantitative measures of fine-tuning [173–178]. One of the simplest measures is the one advocated by Barbieri and Giudice [173] (which was also introduced previously in Ref. [174]),

$$\Delta_i \equiv \left| \frac{\partial \ln m_Z^2}{\partial \ln p_i} \right| , \qquad \Delta \equiv \max\, \Delta_i \,, \tag{88.24}$$

where the p_i are the MSSM parameters at the high-energy scale M_X, which are set by the fundamental SUSY-breaking dynamics. The theory is more fine-tuned as Δ becomes larger. However, different measures of fine-tuning yield quantitatively different results; in particular, calculating minimal fine-tuning based on the high-scale parameters [as defined in Eq. (88.24)] yields a difference by a factor ~ 10 to fine-tuning based on TeV-scale parameters [179, 180].

One can apply the fine-tuning measure to any explicit model of SUSY breaking. For example, in the approaches discussed in Sec. 88.6, the p_i are parameters of the model at the energy scale M_X where the soft SUSY-breaking operators are generated by the dynamics of SUSY breaking. Renormalization group evolution then determines the values of the parameters appearing in Eq. (88.5) at the electroweak scale. In this way, Δ is sensitive to all the SUSY-breaking parameters of the model (see e.g. Ref. [181]). It should be noted that the computation of Δ is often based on Eq. (88.5), which is a tree-level condition. An analysis in Ref. [83], for example, shows that the fine tuning measure can be reduced by as much as a factor of two when loop corrections are included [182].

One way of taking fine-tuning into account in fits to data using Bayesian statistics is to have a prior probability distribution proportional to $1/\Delta$ [183] so that fine-tuning is balanced against the fit to empirical data. In such a Bayesian approach, it is important to choose the prior probability distribution carefully, since prior probability densities that are flat in one set of variables may not be flat in another, more fundamental set. One can in fact derive a different measure of fine-tuning resulting from a Jacobian factor when transforming to other variables.[4] By comparing the results of several Bayesian fits with different (but reasonable) prior probability distributions, one can assess the robustness of the fit with respect to their variation, mitigating for subjectivity in the interpretation of the fine-tuning measure.

As anticipated, there is a tension between the present experimental lower limits on the masses of colored supersymmetric particles [185,186] and the expectation that supersymmetry-breaking is associated with the electroweak symmetry-breaking scale. Moreover, this tension is exacerbated [187] by the observed value of the Higgs mass ($m_h \simeq 125$ GeV), which is not far from the MSSM upper bound ($m_h \lesssim 135$ GeV) [which depends on the top-squark mass and mixing as noted in Sec. 88.5.2]. If $M_{\rm SUSY}$ characterizes the scale of supersymmetric particle masses, then one would crudely expect $\Delta \sim M^2_{\rm SUSY}/m_Z^2$. For example, if $M_{\rm SUSY} \sim 1$ TeV then one expects a $\Delta^{-1} \sim 1\%$ fine-tuning of the MSSM parameters to achieve the observed value of m_Z. This separation of the electroweak symmetry-breaking and SUSY-breaking scales is an example of the little hierarchy problem [188, 189].

The fine-tuning parameter Δ can depend quite sensitively on the structure of the SUSY-breaking dynamics, such as the value of M_X and relations among SUSY-breaking parameters in the fundamental high energy theory [190]. For example, in so-called focus point SUSY models [177, 191], all squark masses can be as heavy as 5 TeV *without* significant fine-tuning. This can be attributed to a focusing behavior of the renormalization group evolution when certain relations hold among the high-energy values of the scalar squared-mass SUSY-breaking parameters. Although the focus point region of the CMSSM still yields an uncomfortably high value of Δ due to the observed Higgs mass of 125 GeV, one can achieve moderate values of Δ in models with NUHM2 boundary conditions for the scalar masses [187].

Among the colored superpartners, the third generation squarks typically have the most significant impact on the naturalness constraints [192], while their masses are the least constrained by the LHC data. Hence, in the absence of any relation between third generation squarks and those of the first two generations, the naturalness constraints due to present LHC data can be considerably weaker than those obtained in the CMSSM. Indeed, models with first and second generation squark masses in the multi-TeV range do not necessarily require significant fine tuning. Such models have the added benefit that undesirable FCNCs mediated by squark exchange are naturally suppressed [193]. Other MSSM mass spectra that are compatible with moderate fine tuning have been considered in Refs. [190] and [194].

The lower bounds on squark and gluino masses may not be as large as suggested by the experimental analyses based on the CMSSM or simplified models. For example, mass bounds for the gluino and the first and second generation squarks based on the CMSSM can often be evaded in alternative or extended MSSM models, *e.g.*, compressed SUSY [195] and stealth SUSY [196]. Moreover, the experimental upper limits for the third generation squark masses (which have a more direct impact on the fine-tuning measure) are weaker than the corresponding mass limits for other colored supersymmetric states.

Among the uncolored superpartners, the higgsinos are typically the most impacted by the naturalness constraints. Eq. (88.5) suggests that the masses of the two neutral higgsinos and charged higgsino pair (which are governed by $|\mu|$) should not be significantly larger than m_Z to avoid an unnatural fine-tuning of the supersymmetric parameters, which would imply the existence of light higgsinos (whose masses are not well constrained, as they are difficult to detect directly at the LHC due to their soft decay products). However, it may be possible to avoid the conclusion that $\mu \sim \mathcal{O}(m_Z)$ if additional correlations among the SUSY breaking mass parameters and μ are present. Such a scenario can be realized in models in which the boundary conditions for SUSY breaking are generated by approximately conformal strong dynamics. For example, in the so-called scalar-sequestering model of Ref. [197], values of $|\mu| > 1$ TeV can be achieved while naturally maintaining the observed value of m_Z.

Finally, one can also consider extensions of the MSSM in which the degree of fine-tuning is relaxed. For example, it has already been noted in Sec. 88.5 that it is possible to accommodate the observed Higgs mass more easily in the NMSSM due to contributions to m_h^2 proportional to the parameter λ^2. This means that we do not have to rely on a large contribution from the radiative corrections to boost the Higgs mass sufficiently above its tree-level bound. This allows for smaller top squark masses, which are more consistent with the demands of naturalness. The reduction of the fine-tuning in various NMSSM models was initially advocated in Ref. [198], and subsequently treated in more detail in Refs. [111, 199]. Naturalness can also be relaxed in extended supersymmetric models with vector-like quarks [200] and in gauge extensions of the MSSM [201].

[4] For example, one may consider the parameters μ and B to be more fundamental than $\tan\beta$ and M_Z. In this case, one would choose a flat prior probability distribution in μ and m^2_{12} rather than in $\tan\beta$ and M_Z [176,184] The Jacobian factor is then obtained from Eq. (88.4) and Eq. (88.5).

The experimental absence of any new physics beyond the Standard Model at the LHC suggests that the principle of naturalness is presently under significant stress [202]. Nevertheless, one must be very cautious when drawing conclusions about the viability of weak-scale SUSY to explain the origin of electroweak symmetry breaking, since different measures of fine-tuning noted above can lead to different assessments [179, 180]. Moreover, the maximal value of Δ that determines whether weak-scale SUSY is a fine-tuned model (should it be $\Delta \sim 10?$ 100? 1000?) is ultimately subjective. Thus, it is premature to conclude that weak-scale SUSY is on the verge of exclusion. It might be possible to sharpen the upper bounds on superpartner masses based on naturalness arguments, which ultimately will either confirm or refute the weak scale SUSY hypothesis [203]. Of course, if evidence for supersymmetric phenomena in the multi-TeV regime were to be established at a future collider facility (with an energy reach beyond the LHC [204]), it would be viewed as a spectacularly successful explanation of the large gauge hierarchy between the (multi-)TeV scale and Planck scale. In this case, the remaining little hierarchy, characterized by the somewhat large value of the fine-tuning parameter Δ discussed above, would be regarded as a less pressing issue.

88.7.2 *Indirect constraints on supersymmetric models*

While direct empirical searches for supersymmetric particles provide various limits on their properties, indirect constraints can depend more sensitively on details of the whole model. The cold dark matter relic density inferred from cosmological fits to observational data is one such example of an indirect constraint. In supersymmetric models where the LSP is a dark matter candidate, its thermally-produced relic density depends upon the scattering of various supersymmetric particles into dark matter particles and SM particles. The resulting relic density can depend sensitively on masses of the non-LSP supersymmetric particle masses. In a typical model, an appreciable region of the parameter space is ruled out because it yields an overabundance of dark matter (see for example Ref. [205] for a fit to a seven parameter version of the pMSSM). However, subsequent model tweaks such as the introduction of R-parity violating effects can mean that the relic density constraint no longer applies to the LSP because it is unstable.

There are a number of indirect constraints based on low-energy measurements that are sensitive to the effects of new physics via supersymmetric loop effects. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous magnetic moment, $a_\mu \equiv \frac{1}{2}(g-2)_\mu$, as reviewed in Ref. [206]. The SM prediction for a_μ, which employs dispersion relations and low energy e^+e^- scattering data to determine the hadronic corrections, exhibits a deviation of 4.2σ from the experimentally observed value [207, 208]. A recent lattice determination [209] of the leading hadronic contribution to the muon magnetic moment yields a smaller deviation from the SM prediction within 1.7σ of the experimental value, although this result has not yet been confirmed by an independent analysis. The 4.2σ deviation is difficult to accommodate in the constrained SUSY models of Sec. 88.6.2 and 88.6.3 given the present sparticle mass bounds [186]. Nevertheless, there are regions of the more general pMSSM parameter space that are consistent with the observed deviation [210].

The precision of the measured value of a_μ is not sensitive to the experimental error associated with the measured value of the fine structure constant, α. In contrast, the comparison of the SM prediction with the experimental measurement of the anomalous magnetic moment of the electron, a_e, depends critically on the value of α. Using the experimentally determined value of α given in Ref. [211] yields a SM prediction for a_e that is 2.4σ above its measured value [212]. However, this previous determination of α is in tension at the 5σ level with a more recent measurement of the fine structure constant [213]. The latter yields a SM prediction for a_e that is 1.6σ below its measured value [213].

Measurements of the fine structure constant, a_e and a_μ jointly constrain the pMSSM parameter space [214] due to shifts originating from supersymmetric loop effects. In particular, if the supersymmetric interpretation of the deviation in the measured value of a_μ from its SM prediction is combined with the experimental limits on the electron electric dipole moment [125], then the resulting upper bounds on MSSM CP-violating phases are even more constraining [215] than previously noted at the beginning of Sec. 88.6.

Flavor anomalies in radiative, leptonic and semi-leptonic b quark decays [216] provide a fertile ground for physics beyond the SM. For example, the rare inclusive decay $b \to s\gamma$ is a sensitive probe of the virtual effects of new physics beyond the SM. The experimental measurements of $B \to X_s + \gamma$ [217] are in agreement with the theoretical SM predictions of Ref. [218]. Since supersymmetric loop corrections can contribute an observable shift from the SM predictions, the absence of any significant deviation places useful constraints on the MSSM parameter space [219].

The rare decays $B_s \to \mu^+\mu^-$ and $B_d \to \mu^+\mu^-$ are especially sensitive to supersymmetric loop effects, with some loop contributions scaling as $\tan^6\beta$ when $\tan\beta \gg 1$ [220]. At present, a combination [221] of the measurements of these rare decay modes [222] are in slight tension at the 2σ level [223] with the predicted SM rates [224]. Such a tension can be resolved by the aforementioned supersymmetric loop effects [220].

Several tensions exist between SM predictions and measurements of some other experimental observables that probe the $b \to s\mu^+\mu^-$ transitions. For example, the ratio of branching ratios $R_K = BR(B \to K\mu^+\mu^-)/BR(B \to Ke^+e^-)$ exhibits a 3.1σ discrepancy in the bin of di-lepton invariant squared mass between 1 GeV^2 and 6 GeV^2 [225] and in the same invariant mass bin, R_{K^*} displays a 2.5σ discrepancy. In addition, a certain angular distribution parameter (denoted by P_5') extracted from $B^0 \to K^{*0}\mu^+\mu^-$ decays [226] deviates from SM predictions by about 4σ. Finally, a 3.6σ deviation is seen in $BR(B_s \to \phi\mu^+\mu^-)$ [227].

The decays $B^\pm \to \tau^\pm\nu_\tau$ and $B \to D^{(*)}\tau^-\overline{\nu}_\tau$ are noteworthy, since in models with extended Higgs sectors such as the MSSM, these processes possess tree-level charged Higgs exchange contributions that can compete with the dominant W-exchange. As Section 72 shows, experimental measurements of $B^\pm \to \tau^\pm\nu_\tau$ are currently consistent with SM expectations [228]. The BaBar Collaboration measured values of the rates for $\overline{B} \to D\tau^-\overline{\nu}_\tau$ and $\overline{B} \to D^*\tau^-\overline{\nu}_\tau$ [229] exhibited a combined 3.4σ discrepancy from the SM predictions, which was also not compatible with the Type-II Higgs Yukawa couplings employed by the MSSM. Subsequent measurements of the LHCb and Belle Collaborations [230] were consistent with the BaBar measurements, although more recent Belle measurements using a semi-leptonic tag are more consistent with SM expectations [231]. The combined difference between the measured and expected values of the $\overline{B} \to D\tau^-\overline{\nu}_\tau$ and $\overline{B} \to D^*\tau^-\overline{\nu}_\tau$ decay rates relative to the corresponding SM values has a significance of about three standard deviations [232]. There are a number of additional anomalies in B decay data that have recently attracted some attention, although at present the observed deviations from SM expectations are mostly at the level of about two to three standard deviations (see, *e.g.*, Ref. [223]).

In summary, although there are a few hints of possible deviations from the SM in B decays, none of the discrepancies by themselves are significant enough to conclusively imply the existence of new physics beyond the SM. Moreover, the absence of evidence for deviations in various B-physics observables from their SM predictions can place useful constraints on the MSSM parameter space [128, 185, 233, 234]. On the other hand, if these deviations were eventually confirmed, then it would be possible to accommodate them in a supersymmetric framework with R-parity violation [235]. If R-parity invariance is maintained (for example, in order to preserve the stability of a LSP dark matter candidate), then a supersymmetric explanation of the B physics anomalies would require significant modifications to the SUSY models treated in this review.

Finally, we note that the constraints from precision electroweak observables (see Sec. 10) and measurements of the ϵ'/ϵ anomaly [236], if it persists [237], in the Kaon system are easily accommodated in models of TeV-scale SUSY [168, 238, 239].

88.8 Massive neutrinos in weak-scale SUSY

In the minimal version of the SM and its supersymmetric extension, there are no right-handed neutrinos, and Majorana

mass terms for the left-handed neutrinos are absent. However, given the overwhelming evidence for neutrino masses and mixing (see Sec. 14 and [240]), any viable model of the fundamental particles must provide a mechanism for generating neutrino masses [241]. In extended supersymmetric models, various mechanisms exist for producing massive neutrinos [242]. Although one can devise models for generating massive Dirac neutrinos [243], the most common approaches for incorporating neutrino masses are based on L-violating supersymmetric extensions of the MSSM, which generate massive Majorana neutrinos. Two classes of L-violating supersymmetric models will now be considered.

88.8.1 *The supersymmetric seesaw*

Neutrino masses can be incorporated into the SM by introducing SU(3)×SU(2)×U(1) singlet right-handed neutrinos (ν_R) whose mass parameters are very large, typically near the grand unification scale. In addition, one must also include a standard Yukawa couplings between the lepton doublets, the Higgs doublet, and ν_R. The Higgs vacuum expectation value then induces an off-diagonal ν_L–ν_R mass on the order of the electroweak scale. Diagonalizing the neutrino mass matrix (in the three-generation model) yields three superheavy neutrino states, and three very light neutrino states that are identified with the light neutrinos observed in nature. This is the seesaw mechanism [244].

It is straightforward to construct a supersymmetric generalization of the seesaw model of neutrino masses [245,246] by promoting the right-handed neutrino field to a superfield $\widehat{N}^c = (\widetilde{\nu}_R\,;\,\nu_R)$. Integrating out the heavy right-handed neutrino supermultiplet yields a new term in the superpotential [cf. Eq. (88.1)] of the form

$$W_{\rm seesaw} = \frac{f}{M_R}(\widehat{H}_U\widehat{L})(\widehat{H}_U\widehat{L})\,, \tag{88.25}$$

where M_R is the mass scale of the right-handed neutrino sector and f is a dimensionless constant. Note that lepton number is broken by two units by Eq. (88.25), which implies that R-parity invariance is preserved. The supersymmetric analogue of the Majorana neutrino mass term in the sneutrino sector leads to sneutrino–antisneutrino mixing phenomena [246,247]. The right-handed sneutrino that resides in $\widehat{L}$ also provides an intriguing dark matter candidate [248].

The SUSY Les Houches Accord [76,94], mentioned at the end of the introduction to Sec. 88.4, has been extended to the supersymmetric seesaw (and other extensions of the MSSM) in Ref. [249].

88.8.2 *R-parity-violating SUSY*

It is possible to incorporate massive neutrinos in renormalizable supersymmetric models while retaining the minimal particle content of the MSSM by relaxing the assumption of R-parity invariance. The most general R-parity-violating model involving the MSSM spectrum introduces many new parameters to both the SUSY-conserving and the SUSY-breaking sectors [76, 250]. Each new interaction term violates either B or L conservation. For example, starting from the MSSM superpotential given in Eq. (88.1) [suitably generalized to three generations of quarks, leptons and their superpartners], consider the effect of adding the following new terms:

$$\begin{aligned} W_{\rm RPV} =& (\lambda_L)_{pmn}\widehat{L}_p\widehat{L}_m\widehat{E}^c_n + (\lambda'_L)_{pmn}\widehat{L}_p\widehat{Q}_m\widehat{D}^c_n \\ &+ (\lambda_B)_{pmn}\widehat{U}^c_p\widehat{D}^c_m\widehat{D}^c_n + (\mu_L)_p\widehat{H}_u\widehat{L}_p\,, \end{aligned} \tag{88.26}$$

where p, m, and n are generation indices, and gauge group indices are suppressed. Eq. (88.26) yields new scalar-fermion Yukawa couplings consisting of all possible combinations involving two SM fermions and one scalar superpartner.

Note that the term in Eq. (88.26) proportional to λ_B violates B, while the other three terms violate L. The L-violating term in Eq. (88.26) proportional to μ_L is the RPV analog of the $\mu\widehat{H}_u\widehat{H}_d$ term of the MSSM superpotential, in which the $Y = -1$ Higgs/higgsino supermultiplet $\widehat{H}_d$ is replaced by the slepton/lepton supermultiplet $\widehat{L}_p$.

Phenomenological constraints derived from data on various low-energy B- and L-violating processes can be used to establish limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda'_L)_{pmn}$, and $(\lambda_B)_{pmn}$ taken one at a time [250, 251]. If more than one coefficient is simultaneously non-zero, then the limits are in general more complicated [252]. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose B or L invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which B is conserved, but L is violated. It is possible to enforce baryon number conservation (and the stability of the proton), while allowing for lepton-number-violating interactions by imposing a discrete $\mathbb{Z}_3$ baryon triality symmetry on the low-energy theory [253], in place of the standard $\mathbb{Z}_2$ R-parity. Since the distinction between the Higgs and matter supermultiplets is lost in RPV models where L is violated, the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos are now possible, leading to more complicated mass matrices and mass eigenstates than in the MSSM. The treatment of neutrino masses and mixing in this framework can be found, *e.g.*, in Ref. [254].

Alternatively, one can consider imposing a lepton parity such that all lepton superfields are odd [253, 255]. In this case, only the B-violating term in Eq. (88.26) survives, and L is conserved. Models of this type have been considered in Ref. [256]. Since L is conserved in these models, the mixing of the lepton and Higgs superfields is forbidden. Moreover, neutrino masses (and mixing) are not generated if lepton parity is an exact symmetry. However, one expects that lepton parity cannot be exact due to quantum gravity effects. Remarkably, the standard $\mathbb{Z}_2$ R-parity and the $\mathbb{Z}_3$ baryon triality are stable with respect to quantum gravity effects, as they can be identified as residual discrete symmetries that arise from spontaneously broken non-anomalous gauge symmetries [253].

The symmetries employed above to either remove or suppress R-parity violating operators were flavor independent. In contrast, there exist a number of motivated scenarios based on flavor symmetries that can also yield the suppression as required by the experimental data (e.g., see Ref. [257]).

The supersymmetric phenomenology of the RPV models exhibits features that are distinct from that of the MSSM [250]. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. A comprehensive examination of the phenomenology of the MSSM extended by a single R-parity violating coupling at the unification scale and its implications for LHC searches has been given in Ref. [258]. As an example, the sparticle mass bounds obtained in searches for R-parity-conserving SUSY can be considerably relaxed in certain RPV models due to the absence of large missing transverse momentum signatures [259]. This can alleviate some of the tension with naturalness (introduced in Sec. 88.7.1).

Nevertheless, the loss of the missing-energy signature is often compensated by other striking signals (which depend on which R-parity-violating parameters are dominant). For example, supersymmetric particles in RPV models can be singly produced (in contrast to R-parity-conserving models where supersymmetric particles must be produced in pairs). The phenomenology of pair-produced supersymmetric particles is also modified in RPV models due to new decay chains not present in R-parity-conserving SUSY models [250].

In RPV models with lepton number violation (these include weak-scale SUSY models with baryon triality mentioned above), both $\Delta L = 1$ and $\Delta L = 2$ phenomena are allowed, leading to neutrino masses and mixing [260], neutrinoless double-beta decay [261], sneutrino-antisneutrino mixing [262], and resonant s-channel production of sneutrinos in e^+e^- collisions [263] and in charged sleptons in $p\bar{p}$ and pp collisions [264], respectively.

88.9 Extensions beyond the MSSM

Extensions of the MSSM have been proposed to solve a variety of theoretical problems. One such problem involves the μ parameter of the MSSM. Although μ is a SUSY-*preserving* parameter, it must be of order the effective SUSY-breaking scale of the MSSM

to yield a consistent supersymmetric phenomenology [265]. Any natural solution to the so-called μ-problem must incorporate a symmetry that enforces $\mu = 0$ and a small symmetry-breaking parameter that generates a value of μ that is not parametrically larger than the effective SUSY-breaking scale [266]. A number of proposed mechanisms in the literature (*e.g.*, see Refs. [265–267]) provide concrete examples of a natural solution to the μ-problem of the MSSM.

In extensions of the MSSM, new compelling solutions to the μ-problem are possible. For example, one can replace μ by the vacuum expectation value of a new SU(3)×SU(2)×U(1) singlet scalar field, as noted below Eq. 88.15. This is the NMSSM, which yields phenomena that were briefly discussed in Sections 88.4–88.7. The NMSSM superpotential consists only of trilinear terms whose coefficients are dimensionless. There are some advantages to extending the NMSSM further to the 'USSM' [102] by adding a new broken U(1) gauge symmetry [268], under which the singlet field is charged.

Alternatively, one can consider a generalized version of the NMSSM (called the GNMSSM in Ref. [199]), where all possible renormalizable terms in the superpotential are allowed, which yield new supersymmetric mass terms (analogous to the μ term of the MSSM). A discussion of the parameters of the GNMSSM can be found in Ref. [76]. Although the GNMSSM does not solve the μ-problem, it does exhibit regions of parameter space in which the degree of fine-tuning is relaxed, as discussed in Sec. 88.7.1.

The generation of the μ term may be connected with the solution to the strong CP problem [269]. Models of this type, which include new gauge singlet fields that are charged under the Peccei-Quinn (PQ) symmetry [270], were first proposed in Ref. [265]. The breaking of the PQ symmetry is thus intimately tied to SUSY breaking, while naturally yielding a value of μ that is of order the electroweak symmetry breaking scale [271].

All supersymmetric models discussed so far in this review possess self-conjugate fermions—the Majorana gluinos and neutralinos. However, it is possible to add additional chiral superfields in the adjoint representation. The spin-1/2 components of these new superfields can pair up with the gauginos to form Dirac gauginos [272,273]. Such states appear in models of so-called supersoft SUSY breaking [274], in some generalized GMSB models [275], and in R-symmetric SUSY models [276, 277]. Such approaches often lead to improved naturalness and/or significantly relaxed flavor constraints. The implications of models of Dirac gauginos on the observed Higgs boson mass and its properties are addressed in Ref. [278].

For completeness, we briefly note other MSSM extensions considered in the literature. These include an enlarged electroweak gauge group beyond SU(2)×U(1) [279]; the addition of new Higgs supermultiplets beyond the doublets and singlets of the MSSM/NMSSM [280]; and/or the addition of new (possibly exotic) matter supermultiplets [200, 281, 282] such as vector-like fermions and their superpartners.

89. Supersymmetry, Part II (Experiment)

Revised September 2021 by M. D'Onofrio (Liverpool U.) and F. Moortgat (CERN; Ghent U.).

89.1 Introduction

Supersymmetry (SUSY), a transformation relating fermions to bosons and vice versa [1–9] is one of the most compelling possible extensions of the Standard Model of particle physics (SM).

On theoretical grounds SUSY is motivated as a generalization of space-time symmetries. A low-energy realization of SUSY, *i.e.*, SUSY at the TeV scale, is, however, not a necessary consequence. Instead, low-energy SUSY is motivated by the possible cancellation of quadratic divergences in radiative corrections to the Higgs boson mass [10–15]. Furthermore, it is intriguing that a weakly interacting, (meta)stable supersymmetric particle might make up some or all of the dark matter in the Universe [16–18]. In addition, SUSY predicts that gauge couplings, as measured experimentally at the electroweak scale, unify at an energy scale $\mathcal{O}(10^{16})$ GeV ("GUT scale") near the Planck scale [19–25].

In the minimal supersymmetric extension to the Standard Model, the so called MSSM [11, 26, 27], a supersymmetry transformation relates every chiral fermion and gauge boson in the SM to a supersymmetric partner with half a unit of spin difference, but otherwise with the same properties (such as mass) and quantum numbers. The MSSM Higgs sector contains two doublets, which give mass to the up-type and down-type quarks, respectively. After electroweak symmetry breaking, five Higgs bosons arise, of which two are charged. The supersymmetric partners of chiral fermions are squarks ($\tilde{q}$) and sleptons ($\tilde{\ell}$, $\tilde{\nu}$), and the "gauginos" for gauge bosons. The supersymmetric partners of the Higgs doublets are known as "higgsinos." The weak gauginos and higgsinos mix, giving rise to charged mass eigenstates called "charginos" ($\tilde{\chi}^{\pm}$), and neutral mass eigenstates called "neutralinos" ($\tilde{\chi}^{0}$). These are often collectively referred to as electroweakinos (EWkinos). The SUSY partners of the gluons are known as "gluinos" ($\tilde{g}$). The fact that such particles are not yet observed leads to the conclusion that, if supersymmetry is realized, it is a broken symmetry. A description of SUSY in the form of an effective Lagrangian with only "soft" SUSY breaking terms and SUSY particle masses of the order of TeV maintains the cancellation of quadratic divergences of soft SUSY breaking scalar mass squared parameters.

The phenomenology of SUSY is to a large extent defined by the SUSY breaking mechanism and the SUSY breaking scale. These determine the SUSY particle masses, the mass hierarchy, the field contents of physical particles, and their decay modes. In addition, phenomenology crucially depends on whether the multiplicative quantum number of R-parity [27], $R = (-1)^{3(B-L)+2S}$, where B and L are baryon and lepton numbers and S is the spin, is conserved or violated. If R-parity is conserved, SUSY particles (sparticles), which have odd R-parity, are produced in pairs and the decays of each SUSY particle must involve an odd number of lighter SUSY particles. The lightest SUSY particle (LSP) is then stable and often assumed to be a weakly interacting massive particle (WIMP). If R-parity is violated, new terms λ_{ijk}, λ'_{ijk} and λ''_{ijk} appear in the superpotential, where ijk are generation indices; λ-type couplings appear between lepton superfields only, λ''-type are between quark superfields only, and λ'-type couplings connect the two. R-parity violation implies lepton and/or baryon number violation. More details of the theoretical framework of SUSY are discussed elsewhere in this volume [28].

The discovery of a Higgs boson with a mass around 125 GeV imposes constraints on SUSY models, which are discussed elsewhere [28, 29]. Low-energy data from flavor physics experiments, high-precision electroweak observables as well as astrophysical data also impose strong constraints on the allowed SUSY parameter space. Recent examples of such data include measurements of the rare B-meson decay $B_s \to \mu^+\mu^-$ [30–32], measurements of the anomalous magnetic moment of the muon [33, 34], and accurate determinations of the cosmological dark matter relic density constraint [35, 36].

Indirect constraints can be more sensitive to higher SUSY mass scales than experiments searching for direct sparticle production at colliders, but the interpretation of these results is often strongly model dependent. In contrast, direct searches for sparticle production at collider experiments, which are the main topic of this review, are less subject to interpretation ambiguities and therefore they play a crucial role in the search for SUSY.

89.2 Overview of the experimental search programme

The electron-positron collider LEP was operational at CERN between 1989 and 2000. In the initial phase, center-of-mass energies around the Z-peak were probed, but after 1995 the LEP experiments collected a significant amount of luminosity at higher center-of-mass energies, some 235 pb^{-1} per experiment at $\sqrt{s} \geq 204$ GeV, with a maximum $\sqrt{s}$ of 209 GeV. Searches for new physics at e^+e^- colliders benefit from the clean experimental environment and the fact that momentum balance can be measured not only in the plane transverse to the beam, but also in the direction along the beam (up to the beam pipe holes), defined as the longitudinal direction. Searches at LEP are dominated by the data samples taken at the highest center-of-mass energies.

The CDF and D0 experiments at the Tevatron, a proton-antiproton collider at a center-of-mass energy of up to 1.96 TeV, had an extensive search program for supersymmetric particles. CDF and D0 collected integrated luminosities between 10 and 11 fb^{-1} each up to the end of collider operations in 2011.

The electron-proton collider HERA provided collisions to the H1 and ZEUS experiments between 1992 and 2007, at a center-of-mass energy up to 318 GeV. A total integrated luminosity of approximately 0.5 fb^{-1} was collected by each experiment. Since at HERA baryons collide with leptons, SUSY searches at HERA typically look for R-parity violating production of single SUSY particles.

The Large Hadron Collider (LHC) at CERN started proton-proton operation at a center-of-mass energy of 7 TeV in 2010. By the end of 2011 the ATLAS and CMS experiments had collected about 5 fb^{-1} of integrated luminosity each, and the LHCb experiment had collected approximately 1 fb^{-1}. In 2012, the LHC operated at a center-of-mass energy of 8 TeV, and ATLAS and CMS collected approximately 20 fb^{-1} each, whereas LHCb collected 2 fb^{-1}. In 2015, the LHC started Run 2, with a center-of-mass energy of 13 TeV. At the end of Run 2 in November 2018, ATLAS and CMS had both collected approximately 140 fb^{-1}, and LHCb had collected almost 6 fb^{-1}.

At the LHC, cross sections of QCD-mediated processes are the largest achievable at colliders, which is reflected in the higher sensitivity for SUSY particles carrying color charge, squarks and gluinos, with respect to LEP, Tevatron and HERA. In particular, proton-proton collisions at the LHC differ from proton-antiproton collisions at the Tevatron in the sense that there are no valence anti-quarks in the proton, and that gluon-initiated processes play a more dominant role. The increased center-of-mass energy of the LHC compared to the Tevatron significantly extends the kinematic reach for SUSY searches. This is reflected foremost in the sensitivity for squarks and gluinos, but also for SUSY particles produced via electroweak processes.

In this review we report results of direct searches for SUSY particles at colliders up to August 2021, mostly covering data analyses at the ATLAS and CMS experiments with reference to results from LEP, HERA and the Tevatron. For more details on LEP and Tevatron constraints, see earlier PDG reviews [37]. Results are categorized depending on the targeted SUSY particles, the nature of their production and decays, and the assumption on R-parity. Brief summaries of search techniques and approaches adopted for interpretation of the results are given in Section 89.3 and 89.4, respectively. Sections 89.5-89.9 focus on results for promptly-decaying gluinos and first and second generation squarks, top and bottom squarks, electroweakinos (charginos, neutralinos) and sleptons. Limits obtained for sparticle masses assuming R-parity violating models are also reported. Results of dedicated searches for long-lived (LL) SUSY particles are reported in Section 89.10. Finally, Section 89.11 provides examples of global reinterpretations of SUSY searches.

	N_j	t_{mod}	M_{lb} [GeV]
A	2–3	> 10	≤ 175
B	2–3	> 10	> 175
C	≥ 4	≤ 0	≤ 175
D	≥ 4	≤ 0	> 175
E	≥ 4	0–10	≤ 175
F	≥ 4	0–10	> 175
G	≥ 4	> 10	≤ 175
H	≥ 4	> 10	> 175

Figure 89.1: Example of multiple signal regions set for a typical SUSY search at the LHC. For definition of regions and acronyms specific for this search, see corresponding paper.

89.3 Experimental search techniques

Large background contributions from Standard Model processes pose challenges to the trigger and analysis. Such backgrounds are dominated by multijet production processes, including, particularly at the LHC, those of top quark production, as well as jet production in association with vector bosons. The proton momentum is shared between its parton constituents, and in each collision only a fraction of the total center-of-mass energy is available in the hard parton-parton scattering. Since the parton momenta in the longitudinal direction are not known on an event-by-event basis, use of momentum conservation constraints in an analysis is restricted to the transverse plane, leading to the definition of transverse variables, such as the missing transverse momentum, and the transverse mass.

Under the assumption of R-parity conservation (RPC), the typical SUSY search signature for squarks and gluinos at hadron colliders contains high-p_{T} jets, which are produced in the decay chains of heavy squarks and gluinos, and significant missing momentum originating from the two LSPs produced at the end of the decay chains, which escape experimental detection. Electroweakino decays are often characterised by the presence of leptons, for instance from W and Z bosons in the decay chain, plus missing transverse momentum. Standard Model backgrounds with missing transverse momentum include leptonic W/Z-boson decays, associated production of jets and a Z-boson decaying into neutrinos, semi-leptonic heavy-flavor decays to neutrinos, top-quark pair production with one or both W bosons decaying leptonically, and multijet events that may be affected by instrumental effects such as jet mis-measurement.

Selection variables designed to separate the SUSY signal from the Standard Model backgrounds include transverse variables such as H_{T}, $E_{\mathrm{T}}^{\mathrm{miss}}$, and m_{eff}. The quantities H_{T} and $E_{\mathrm{T}}^{\mathrm{miss}}$ refer to the measured transverse energy and the missing transverse momentum in the event, respectively. They are usually defined as the scalar sum of the transverse jet momenta or of the transverse energies of calorimeter clusters measured in the event (H_{T}), or the magnitude ($E_{\mathrm{T}}^{\mathrm{miss}}$) of the negative vector sum of transverse momenta of reconstructed objects like jets and leptons in the event ($\vec{p}_{\mathrm{T}}^{\,\mathrm{miss}}$). The quantity m_{eff} is referred to as the effective mass of the event and is defined as $m_{\mathrm{eff}} = H_{\mathrm{T}} + E_{\mathrm{T}}^{\mathrm{miss}}$. The peak of the m_{eff} distribution for SUSY signal events correlates with the SUSY mass scale, in particular with the mass difference between the primary produced SUSY particle and the LSP [38], whereas the Standard Model backgrounds dominate at low m_{eff}. Additional reduction of multijet backgrounds can be achieved by demanding isolated leptons or photons in the final states; in such events the lepton or photon transverse momentum may be added to H_{T} or m_{eff} for further signal-background separation. Other kinematic variables and approaches developed to increase the sensitivity to pair production of heavy sparticles with TeV-scale masses focusing on the kinematics of their decays are the α_{T} [39–43], *razor* [44], *stransverse mass* (m_{T2}) [45], and *contransverse mass* (m_{CT}) [46] variables. More recently, the topological event reconstruction methods have expanded with the *super-razor* [47] and *recursive jigsaw reconstruction* [48] techniques. Furthermore, the searches for massive SUSY particles frequently attempt to identify their decay into top quarks or vector bosons, which are themselves unstable. If these are produced with a significant boost, jets from their decay will typically overlap, and such topologies are searched for with *jet-substructure* [49] techniques.

Most analyses use simple combinations of selections on kinematic variables (often referred to as *cut-and-count* analyses) and exploit multiple signal regions defined by categorizing events on the basis of several variables and their correlations. An example is provided in Fig. 89.1 from Ref. [50]: 39 signal regions are set to search for top squarks in events with one lepton, jets and missing transverse momentum. Regions depend on jet multiplicities, reconstructed top-quark candidates and thresholds applied to the most discriminant variables used for optimisation.

In recent years, shape analyses or analyses using more sophisticated techniques, e.g. machine learning (ML), have been also developed. ML techniques often allow analyses to better capture the complexity of the events and achieve improved sensitivity with respect to counting experiments. For example, Boosted Decision Trees (BDTs) allow analyses to exploit simultaneously the discriminating power of multiple variables and that of correlations among objects in the events. Deep Neural Networks (NN) are also employed for objects reconstruction and to use directly detector-recorded energies and momenta of produced particles instead of first deriving a restricted set of physical variables. Among others, currently in use are Convolutional NN for image classification techniques, Recurrent NN and Generative Adversarial Networks.

Variables and approaches reported above are also used in searches for R-parity violating (RPV) SUSY models where signal events are often characterised by the presence of multiple leptons and/or jets, and little or no missing transverse momentum. However, if R-parity violating couplings are small, sparticles might be long-lived and may travel macroscopic distances before decaying. Similarly, long lifetimes may be due to small mass splittings, as in the case of pure higgsino/wino scenarios, or to heavy mediators, as in Split SUSY models [51, 52]. The identification of long-lived particles requires dedicated tools and their signatures can be very diverse. At the LHC, customized techniques (also based on NN) have been developed, for example, to reconstruct significantly displaced decay vertices or short track segments, and to identify tracks with atypical properties or unusual ionization, small and localized deposits of energy inside of the calorimeters without associated tracks, or stopped particles that decay out of

time with collisions. For an overview, see Ref. [53].

89.4 Interpretation of search results

Since the mechanism by which SUSY is broken is unknown, a general approach to SUSY via the most general soft SUSY breaking Lagrangian adds a significant number of new free parameters. For the minimal supersymmetric standard model, MSSM, *i.e.*, the model with the minimal particle content, these comprise 105 new real degrees of freedom. A phenomenological analysis of SUSY searches leaving all these parameters free is not feasible. For the practical interpretation of SUSY searches at colliders several approaches are taken to reduce the number of free parameters.

One approach is to assume a SUSY breaking mechanism and lower the number of free parameters through the assumption of additional constraints. Before the start of the LHC, interpretations of experimental results were often performed in constrained models of gravity mediated [54, 55], gauge-mediated [56–58], and anomaly mediated [59, 60] SUSY breaking. The most popular model was the constrained MSSM (CMSSM) [54, 61, 62], which in the literature is also referred to as minimal supergravity, or MSUGRA. These constrained SUSY models are theoretically well motivated and provide a rich spectrum of experimental signatures. However, with universality relations imposed on the soft SUSY breaking parameters, they do not cover all possible kinematic signatures and mass relations of SUSY. Furthermore, LHC Run 1 results, together with other collider and non-collider measurements, limited substantially the allowed SUSY parameter space for these models. This indicates that very constrained models like the CMSSM are no longer good benchmark scenarios to solely characterize the results of SUSY searches at the LHC and efforts have been made to complement them with more flexible approaches.

A broader and more comprehensive subset of the MSSM can be studied via the so-called phenomenological-MSSM, or pMSSM [63–66]. It is derived from the MSSM, using experimental data to eliminate parameters that are free in principle but have already been highly constrained by measurements of *e.g.*, flavor mixing and CP-violation. This effective approach reduces the number of free parameters in the MSSM to typically 19 or even less, making it a practical compromise between the full MSSM and highly constrained models such as the CMSSM.

Even less dependent on fundamental assumptions are interpretations in terms of so-called simplified models [67–70]. Such models assume a limited set of SUSY particle production and decay modes and leave open the possibility to vary masses and other parameters freely. Therefore, simplified models enable comprehensive studies of individual SUSY topologies, and are useful for optimization of the experimental searches over a wide parameter space without limitations on fundamental kinematic properties such as masses, production cross sections, and decay modes.

As a consequence, ATLAS and CMS have adopted simplified models as the primary framework to provide interpretations of their searches. In addition to using simplified models that describe prompt decays of SUSY particles, the experiments are now also focusing more on the use of simplified models that allow for decays of long-lived SUSY particles as they can arise in different SUSY scenarios (see Section 89.10 for further discussion). Today, almost every individual search provides interpretations of their results in one or several simplified models that are characteristic of SUSY topologies probed by the analysis.

While simplified models are very convenient for the interpretation of individual SUSY production and decay topologies, care must be taken when applying these limits to more complex SUSY spectra. In particular, the branching ratio of SUSY particles into a specific final state is often assumed to be 100% and in many of the quoted limits the LSP is assumed to be massless. Therefore, simplified model limits should be seen as an approximation of the constraints that can be placed on sparticle masses in more complex SUSY spectra. Only on a case-by-case basis can it be determined whether the limit of a given simplified model represents a good approximation of the true underlying constraint that can be applied on a sparticle mass in a complex SUSY spectrum. In the following, we will point out explicitly the assumptions that have entered the limits when quoting interpretations from simplified models.

Since none of the searches performed so far have shown significant excess above the SM background prediction, the interpretation of the presented results are exclusion limits on SUSY parameter space. Unless stated differently, all quoted exclusion limits are at 95% confidence level. Finally, we note that many of the recent publications by ATLAS and CMS also present results in terms of model-independent limits such that their discovery potential is statistically quantified independently on a particular model.

89.5 Exclusion limits on gluino, first and second generation squark masses in RPC scenarios

Colored SUSY particles such as squarks and gluinos are produced via the strong interaction and have the highest cross sections at hadron colliders. Limits on squark masses of the order 100 GeV have been set by the LEP experiments [71], in the decay to quark plus neutralino, and for a mass difference between squark and quark plus neutralino of typically at least a few GeV. However, hadron collider experiments are able to set much more stringent mass limits.

The main production mechanisms at hadron colliders are squark-squark, squark-gluino and gluino-gluino production; when "squark" is used "antisquark" is also implied. Pair production usually involves both the s-channel and t-channel parton-parton interactions. However, since there is a negligible amount of bottom and top quark content in the proton, top and bottom squark production proceeds through s-channel diagrams only. Experimental analyses of squark and/or gluino production typically assume the first and second generation squarks to be approximately degenerate in mass. Cross section calculations shown in Fig. 89.2 (from Ref. [72]) assume mass degeneracy of left- and right-handed u, d, s, c squarks. Other sparticle masses are considered decoupled. The LHC experiments have started to also provide simplified model limits on individual first or second generation squarks. Top and bottom squarks have the same production cross section, equivalent to that of a single light squark.

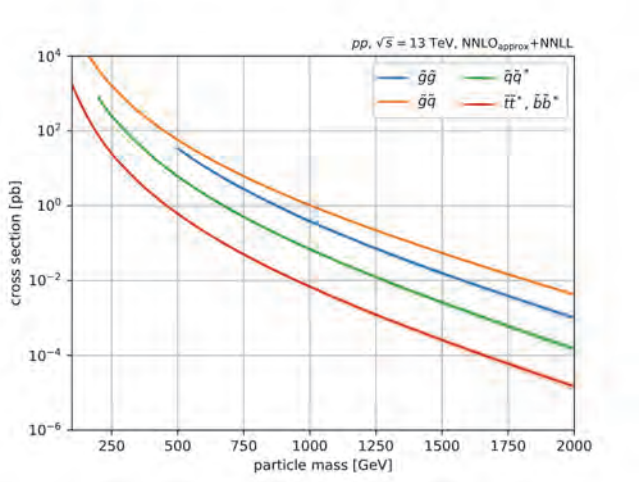

Figure 89.2: Cross sections for pair production of gluinos and squarks as a function of their mass at the LHC for a center-of-mass energy of 13 TeV. They are calculated at approximately next-to-next-to-LO (NNLO) including the resummation of soft gluon emission at the next-to-next-to-leading logarithmic accuracy (NNLO$_{\text{approx}}$+NNLL).

In this section, we focus on results assuming R-parity conservation. Limits set by the Tevatron experiments on the gluino mass assume the framework of the CMSSM, with $\tan\beta = 5$ (CDF) or $\tan\beta = 3$ (D0). Furthermore, the common trilinear term A_0 is set to 0 and the higgsino mass term μ is assumed to be less than 0. The resulting lower mass limits are about 310 GeV for all squark masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{g}}$ [73, 74]. These limits have been superseded by those provided by ATLAS and CMS, and the tightest constraints have been set with up to approximately

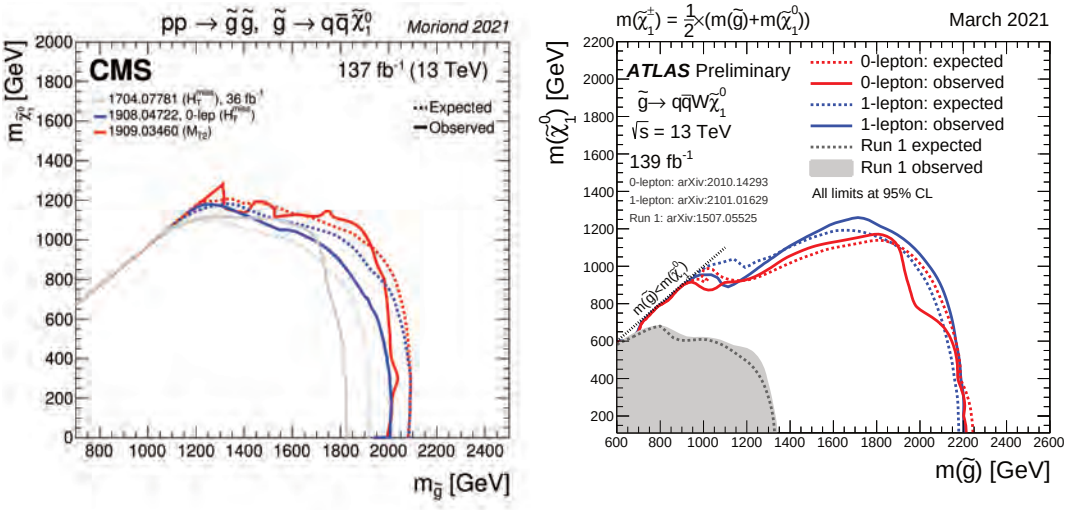

Figure 89.3: Lower mass limits, at 95% C.L., on gluino pair production for various decay chains in the framework of simplified models. Left: $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$, result of the CMS collaboration. Right: $\tilde{g} \to q\bar{q}W\tilde{\chi}_1^0$, result of the ATLAS collaboration.

140 fb^{-1} of data recorded at the LHC at a center-of-mass energy of 13 TeV.

ATLAS and CMS limits on the gluino mass have been established in the framework of simplified models. Assuming only gluino pair production, three main primary decay chains of the gluino have been considered by the LHC experiments for interpretations of their search results. The first decay chain, $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$, assumes gluino mediated production of first and second generation squarks (on-shell or off-shell) which leads to four light flavor quarks in the final state. Therefore, inclusive all-hadronic analyses searching for multijet plus $E_{\mathrm{T}}^{\mathrm{miss}}$ final states are utilized to put limits on this simplified model. These limits are derived as a function of the gluino and neutralino (LSP) mass. As shown in Fig. 89.3 (left)the CMS collaboration [75] excludes in this simplified model gluino masses below approximately 2.1 TeV for a light neutralino mass below about 600 GeV. In scenarios where neutralinos are not very light, the efficiency of the analyses is reduced by the fact that jets are less energetic, and there is less missing transverse momentum in the event. This leads to weaker limits when the mass difference $\Delta m = m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$ is reduced. For example, for neutralino masses above about 1.2 TeV no limit on the gluino mass can be set for this decay chain. Therefore, limits on gluino masses are strongly affected by the assumption of the neutralino mass. Similar results for this simplified model have been obtained by ATLAS [76]. A second simplified model postulates a decay chain where $\tilde{g} \to q\bar{q}W\tilde{\chi}_1^0$, assuming that the intermediate (on-shell or off-shell) squark is left-handed and decays to a chargino and a quark, with the chargino decaying to a W boson and the LSP. This leads to two W bosons and four light flavor quarks plus $E_{\mathrm{T}}^{\mathrm{miss}}$ in the final state. Both leptonic and hadronic decays of the W can be considered. In this scenario, the ATLAS collaboration [77, 78] excludes gluino masses below approximately 2.2 TeV for a sufficiently light neutralino and assuming the chargino mass is halfway between the gluino and neutralino mass, see Fig. 89.3 (right). Again, for neutralino masses above about 1.2 TeV, there exists no limit on the gluino mass for this decay chain. Similar results have been obtained by the CMS collaboration [79].

Gluino decays are not limited to first and second generation squarks: another important decay chain of the gluino considered for interpretation in simplified models is $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$. In this case the decay is mediated via bottom squarks and thus leads to four jets from b quarks and $E_{\mathrm{T}}^{\mathrm{miss}}$ in the final state. For this topology as well, inclusive all-hadronic searches provide the highest sensitivity. However, with four b-quarks in the final state, the use of secondary vertex reconstruction for the identification of jets originating from b-quarks provides a powerful handle on the SM background. Therefore, in addition to a multijet plus $E_{\mathrm{T}}^{\mathrm{miss}}$ signature these searches also require several jets to be tagged as b-jets. As shown in Fig. 89.4 (left), for this simplified model CMS [75] excludes gluino masses below ≈ 2.3 TeV for a sufficiently light neutralino, while for neutralino masses above ≈ 1.5 TeV no limit on the gluino mass can be set. Comparable limits for this simplified model are provided by searches from ATLAS [80].

If kinematically allowed, decays of gluinos to top squarks via $\tilde{g} \to \tilde{t}t$ are also possible. This leads to a "four tops" final state, $ttttt\tilde{\chi}_1^0\tilde{\chi}_1^0$, and defines the next important simplified model characterizing gluino pair production, $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$, . The topology of this decay is very rich in different experimental signatures: as many as four isolated leptons, four b-jets, several light flavor quark jets, and significant missing transverse momentum from the neutrinos in the W decay and from the two neutralinos. As shown in Fig. 89.4 (right), the ATLAS search [80] rules out gluinos with masses below ≈ 2.25 TeV for light neutralinos in this model. For neutralino masses above ≈ 1.2 TeV, no limit can be placed on the gluino mass. The CMS multiple b-jet search [81] obtains similar limits.

Assuming gluinos to be heavier than squarks, squarks will predominantly decay to a quark and a neutralino or chargino, if kinematically allowed. The decay may involve the lightest neutralino (typically the LSP) or chargino, but, depending on the masses and couplings of the gauginos and on the handedness of the squarks, may involve heavier neutralinos or charginos. For pair production of first and second generation squarks, the simplest decay modes involve two jets and missing transverse momentum, with potential extra jets stemming from initial state or final state radiation (ISR/FSR) or from decay modes with longer decay chains (cascades). In cascades, isolated photons or leptons may appear from the decays of sparticles such as neutralinos or charginos. Final states are thus characterized by significant missing transverse momentum, and at least two, and possibly many more high p_{T} jets, which can be accompanied by one or more isolated objects like photons or leptons, including τ leptons, in the final state.

Limits on first and second generation squark masses set by the Tevatron experiments assume the CMSSM, and amount to lower limits of about 380 GeV for all gluino masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{g}}$ [73, 74].

At the LHC, limits on squark masses have been set using up to approximately 140 fb^{-1} of data at 13 TeV. Interpretations in simplified models typically characterize squark pair production with only one decay chain of $\tilde{q} \to q\tilde{\chi}_1^0$. Here it is assumed that the left and right-handed $\tilde{u}$, $\tilde{d}$, $\tilde{s}$ and $\tilde{c}$ squarks are degenerate in mass. Furthermore, it is assumed that the mass of the gluino is very high and thus contributions of the corresponding t-channel diagrams to squark pair production are negligible. Therefore, the total production cross section for this simplified model is eight

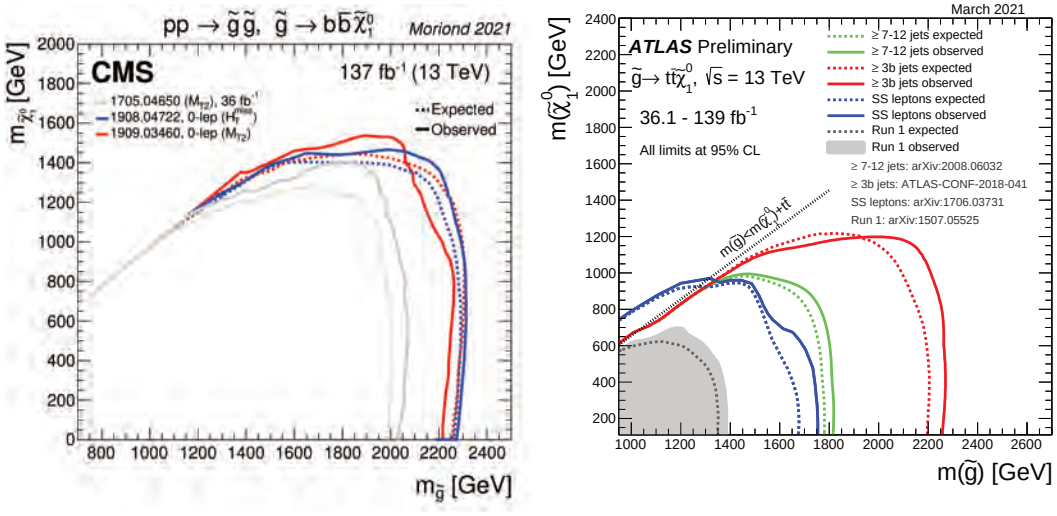

Figure 89.4: Lower mass limits, at 95% C.L., on gluino pair production for various decay chains in the framework of simplified models. Left: $\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$. Right: $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$. Results from the CMS and ATLAS collaborations.

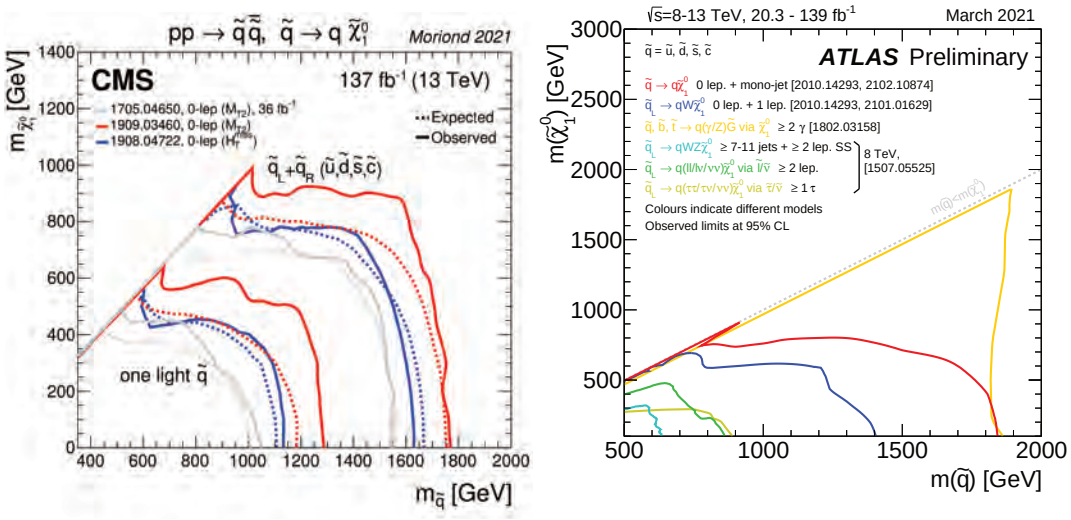

Figure 89.5: Left: 95% C.L. exclusion contours in the framework of simplified models assuming a single decay chain of $\tilde{q} \to q\tilde{\chi}_1^0$, obtained by the CMS collaboration. Right: Assuming more complicated decay chains including W or Z bosons, obtained by the ATLAS collaboration.

times the production cross section of an individual squark (e.g. $\tilde{u}_L$). Under these assumptions, CMS obtains a lower squark mass limit of ≈ 1.75 TeV for light neutralinos [81], as shown in Fig. 89.5 (left). The effects of heavy neutralinos on squark limits are similar to those discussed in the gluino case, and only for neutralino masses below $\approx$ 800 GeV can any squark masses be excluded. Searches for new physics in monojet channels are sensitive to very compressed scenarios, and masses up to 900 GeV are excluded for $\Delta m = m_{\tilde{q}}, m_{\tilde{\chi}_1^0} \approx 5$ GeV [82].

If the assumption of mass degenerate first and second generation squarks is dropped and only the production of a single light squark is assumed, the limits weaken significantly. For example, the CMS limit on degenerate squarks of 1750 GeV for light neutralinos drops to $\approx$ 1300 GeV for pair production of a single light squark, and for neutralinos heavier than $\approx$ 600 GeV no squark mass limit can be placed. It should be noted that this limit is not a result of a simple scaling of the above mentioned mass limits assuming eight-fold mass degeneracy but it also takes into account that for an eight times lower production cross section the analyses must probe kinematic regions of phase space that are closer to the ones of SM background production.

The results of the ATLAS searches for more complicated decay chains, where e.g. intermediate bosons are produced as well [76], can be seen in Fig. 89.5 (right). Depending on the topology, the exclusion limit can reach up to ≈ 2 TeV (this value is only reached in gaugino-mediated simplified models).

For single light squarks ATLAS also reports results of a dedicated search for pair production of scalar partners of charm quarks [83]. Assuming that the scalar-charm state exclusively decays into a charm quark and a neutralino, scalar-charm masses up to 800 GeV are excluded for neutralino masses below 260 GeV.

A summary of the most important squark and gluino mass limits for different interpretation approaches assuming R-parity conservation is shown in Table 89.1. For gluino masses rather similar limits of about 2.3 TeV are obtained from different model assumptions, indicating that the LHC is indeed probing direct gluino production at the TeV scale and beyond. However, for neutralino masses above approximately 1.2 to 1.5 TeV, even in the best case scenarios, ATLAS and CMS searches do not place any limits on the gluino mass. Limits on direct squark production, on the other hand, depend strongly on the chosen model. For neutralino masses above $\approx$ 600 GeV no limits on any direct squark pair production scenario are placed by the LHC.

Table 89.1: Summary of squark mass and gluino mass limits using different interpretation approaches assuming R-parity conservation. Masses in this table are provided in GeV. Further details about the assumptions and analyses from which these limits are obtained are discussed in the corresponding sections of the text.

Model	Assumption	$m_{\tilde{q}}$	$m_{\tilde{g}}$
Simplified models $\tilde{g}\tilde{g}$			
$\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	-	≈ 2300
	$m_{\tilde{\chi}_1^0} > \approx 1200$	-	no limit
$\tilde{g} \to b\bar{b}\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	-	≈ 2300
	$m_{\tilde{\chi}_1^0} > \approx 1500$	-	no limit
$\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	-	≈ 2250
	$m_{\tilde{\chi}_1^0} > \approx 1300$	-	no limit
Simplified models $\tilde{q}\tilde{q}$			
$\tilde{q} \to q\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	≈ 1900	-
	$m_{\tilde{\chi}_1^0} > \approx 800$	no limit	-
$\tilde{u}_L \to q\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	≈ 1300	-
	$m_{\tilde{\chi}_1^0} > \approx 600$	no limit	-

89.6 Exclusion limits on bottom and top squarks masses in RPC scenarios

Besides placing stringent limits on first and second generation squark masses, the LHC experiments also search for the production of third generation squarks. SUSY at the TeV-scale is often motivated by naturalness arguments, most notably as a solution to cancel quadratic divergences in radiative corrections to the Higgs boson mass. In this context, the most relevant terms for SUSY phenomenology arise from the interplay between the masses of the third generation squarks and the Yukawa coupling of the top quark to the Higgs boson. This motivates a potential constraint on the masses of the top squarks and the left-handed bottom squark. Due to the large top quark mass, significant mixing between $\tilde{t}_L$ and $\tilde{t}_R$ is expected, leading to a lighter mass state $\tilde{t}_1$ and a heavier mass state $\tilde{t}_2$. In the MSSM, the lightest top squark ($\tilde{t}_1$) can be the lightest squark.

Bottom squarks are expected to decay predominantly to $b\tilde{\chi}_1^0$ giving rise to the characteristic multi b-jet and E_T^{miss} signature. Direct production of bottom squark pairs has been searched for at the Tevatron and at the LHC. Limits from the Tevatron are $m_{\tilde{b}} > 247$ GeV for a massless neutralino [84, 85]. The LHC experiments have surpassed these limits and are well above 1 TeV, and the latest results, shown in Fig. 89.6 (left), are based on up to 140 fb^{-1} of data collected at $\sqrt{s} = 13$ TeV. ATLAS has set a lower limit of $m_{\tilde{b}} > 1250$ GeV for massless neutralinos in this model [86] exploiting the two b-jets and missing transverse momentum analysis. For $m_{\tilde{\chi}_1^0} \approx 800$ GeV or higher no limit can be placed on direct bottom squark pair production in this simplified model. Limits from CMS are comparable [81]. Reinterpretations of the monojet analysis results can be used to constrain very compressed scenarios, with exclusion of masses up to 550 GeV in case of $\Delta m = m_{\tilde{b}} - m_{\tilde{\chi}_1^0} \approx 5$ GeV [82]. Further bottom squark decay modes have also been searched for by ATLAS [87–89] and CMS [75,90,91], for instance targeting more complex decay chains that include Higgs bosons in the cascade.

The top squark decay modes depend on the SUSY mass spectrum, and on the $\tilde{t}_L$-$\tilde{t}_R$ mixture of the top squark mass eigenstate. If kinematically allowed, the two-body decays $\tilde{t} \to t\tilde{\chi}_1^0$ (which requires $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > m_t$) and $\tilde{t} \to b\tilde{\chi}^{\pm}$ (which requires $m_{\tilde{t}} - m_{\tilde{\chi}^{\pm}} > m_b$) are expected to dominate. If not, the top squark decay may proceed either via the two-body decay $\tilde{t} \to c\tilde{\chi}_1^0$ or through $\tilde{t} \to bf\bar{f}'\tilde{\chi}_1^0$ (where f and $\bar{f}'$ denote a fermion-antifermion pair with appropriate quantum numbers). For $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > m_b$ the latter decay chain represents a four-body decay with a W boson, charged Higgs H, slepton $\tilde{\ell}$, or light flavor squark $\tilde{q}$, exchange. If the exchanged W boson and/or sleptons are kinematically allowed to be on-shell, the three-body decays $\tilde{t} \to Wb\tilde{\chi}_1^0$ and/or $\tilde{t} \to b\nu\tilde{\ell}(\tilde{\nu}\ell)$ will become dominant. For further discussion on top squark decays see for example Ref. [92].

Limits from LEP on the $\tilde{t}_1$ mass are $m_{\tilde{t}} > 96$ GeV in the charm plus neutralino final state, and > 93 GeV in the lepton, b-quark and sneutrino final state [71].

The Tevatron experiments have performed a number of searches for top squarks, often assuming direct pair production. In the $b\ell\tilde{\nu}$ decay channel, and assuming a 100% branching fraction, limits are set as $m_{\tilde{t}} > 210$ GeV for $m_{\tilde{\nu}} < 110$ GeV and $m_{\tilde{t}} - m_{\tilde{\nu}} > 30$ GeV, or $m_{\tilde{t}} > 235$ GeV for $m_{\tilde{\nu}} < 50$ GeV [93, 94]. In the $\tilde{t} \to c\tilde{\chi}_1^0$ decay mode, a top squark with a mass below 180 GeV is excluded for a neutralino lighter than 95 GeV [95, 96]. In both analyses, no limits on the top squark can be set for heavy sneutrinos or neutralinos. In the $\tilde{t} \to b\tilde{\chi}_1^{\pm}$ decay channel, searches for a relatively light top squark have been performed in the dilepton final state [97, 98]. The CDF experiment sets limits in the $\tilde{t} - \tilde{\chi}_1^0$ mass plane for various branching fractions of the chargino decay to leptons and for two values of $m_{\tilde{\chi}_1^{\pm}}$. For $m_{\tilde{\chi}_1^{\pm}} = 105.8$ GeV and $m_{\tilde{\chi}_1^0} = 47.6$ GeV, top squarks between 128 and 135 GeV are excluded for W-like leptonic branching fractions of the chargino.

The LHC experiments have improved these limits substantially. As shown in the right plot of Fig. 89.6, limits on the top squark mass assuming a simplified model with a single decay chain of $\tilde{t} \to t\tilde{\chi}_1^0$ now surpass 1 TeV. The most important searches for this top squark decay topology are dedicated searches requiring zero or one isolated lepton, modest E_T^{miss}, and four or more jets out of which at least one jet must be reconstructed as a b-jet [50,75,81,99–101]. For example, using an all-hadronic analysis, CMS excludes top squarks with masses below about 1300 GeV in this model for light neutralinos, while for $m_{\tilde{\chi}_1^0} > 700$ GeV no limits can be provided [101]. Similar constraints are set by the ATLAS all-hadronic search [99].

Assuming that the top squark decay exclusively proceeds via the chargino mediated decay chain $\tilde{t} \to b\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to W^{\pm(*)}\tilde{\chi}_1^0$ yields stop mass exclusion limits that vary strongly with the assumptions made on the $\tilde{t} - \tilde{\chi}_1^{\pm} - \tilde{\chi}_1^0$ mass hierarchy. For example, for $m_{\tilde{\chi}_1^{\pm}} = (m_{\tilde{t}} + m_{\tilde{\chi}_1^0})/2$, a stop mass below ≈ 1150 GeV for a light $\tilde{\chi}_1^0$ is excluded by CMS, while no limit can be placed for $m_{\tilde{\chi}_1^0} > 550$ GeV [50]. These limits, however, can weaken significantly when other assumptions about the mass hierarchy or the decay of the charginos are imposed [50, 102–104].

Other analyses with zero, one or two leptons target this kinematic region [105–111], also providing sensitivity in the case of alternative decay modes of the top squark, *i.e.* including tau sleptons [104,112,113] or Higgs and Z bosons in the decay chain [114].

If the decays $\tilde{t} \to t\tilde{\chi}_1^0$ and $\tilde{t} \to b\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_1^{\pm} \to W^{\pm(*)}\tilde{\chi}_1^0$ are kinematically forbidden, the decay chains $\tilde{t} \to Wb\tilde{\chi}_1^0$ and $\tilde{t} \to c\tilde{\chi}_1^0$ can become important. The one-lepton ATLAS search provides for the kinematic region $m_{\tilde{t}} - m_{\tilde{\chi}^{\pm}} > m_b + m_W$ lower limits on the top squark mass of ≈ 700 GeV for a neutralino lighter than ≈ 570 GeV [100]. For the kinematic region in which even the production of real W bosons is not allowed, ATLAS and CMS improve the Tevatron limit on $\tilde{t} \to c\tilde{\chi}_1^0$ substantially. Based on a monojet analysis [82] ATLAS excludes top squark masses below $m_{\tilde{\chi}_1^0} \approx 550$ GeV along the kinematic boundary for the $\tilde{t} \to c\tilde{\chi}_1^0$ decay. The ATLAS monojet analysis also places similar boundaries for the other decay chain relevant in this phase region, $\tilde{t} \to bf\bar{f}'\tilde{\chi}_1^0$. Other analyses, such as the search in events with one leptons and jets, are also sensitive to this decay mode: the ATLAS one-lepton analysis excludes up to ≈ 650 GeV for $\Delta m = m_{\tilde{t}}, m_{\tilde{\chi}_1^0} \approx 50$ GeV [100]. The CMS collaboration uses the hadronic searches [101, 106, 108] to place constraints on stop decay into charm-quark and excludes $m_{\tilde{t}} \approx 630$ GeV for $\Delta m = m_{\tilde{t}}, m_{\tilde{\chi}_1^0} \approx 50$ GeV [101]. The same constraints are set in case of $\tilde{t} \to bf\bar{f}'\tilde{\chi}_1^0$, with CMS excluding $m_{\tilde{t}} \approx 640$ GeV for

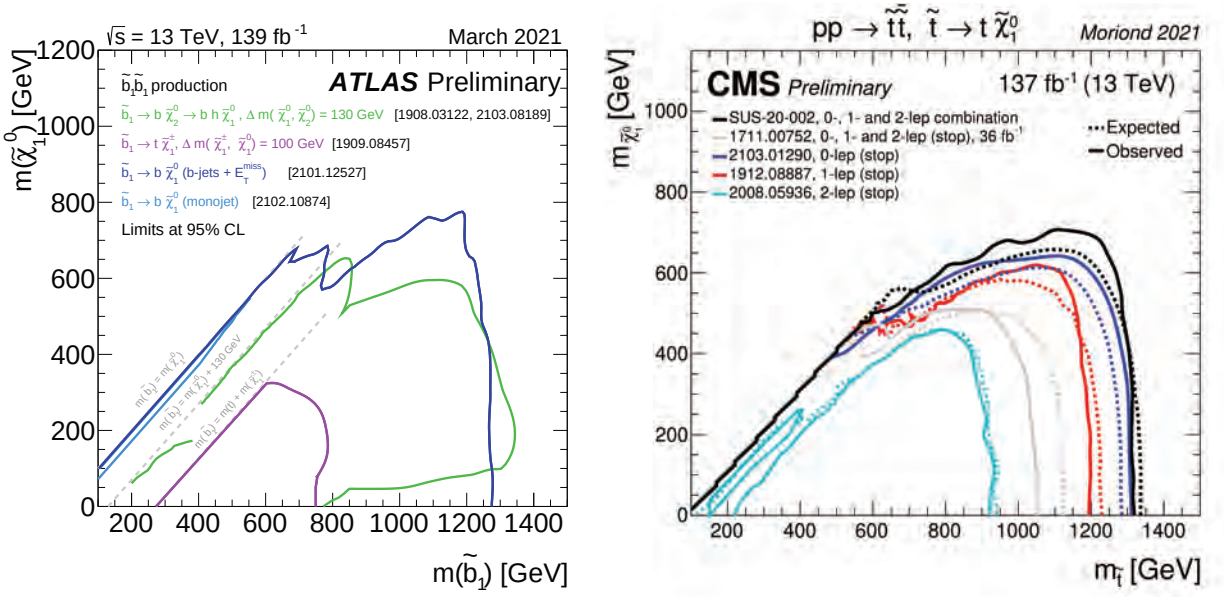

Figure 89.6: Left: A summary of the 95% C.L. exclusion contours in the sbottom-neutralino mass plane for various possible decay chains as obtained in dedicated analyses by ATLAS. Right: The 95% C.L. exclusion contours in the stop-neutralino mass plane defined in the framework of a simplified model assuming a single decay chain of $\tilde{t} \to t\tilde{\chi}_1^0$ as obtained by CMS.

$\Delta m = m_{\tilde{t}}, m_{\tilde{\chi}_1^0} \approx 50$ GeV [101].

Table 89.2: Summary of bottom and top squark mass limits using different interpretation approaches assuming R-parity conservation. Masses in this table are provided in GeV. Further details about the assumptions and analyses from which these limits are obtained are discussed in the corresponding sections of the text.

Model	Assumption	$m_{\tilde{q}}$
$\tilde{b} \to b\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	≈ 1250
	$m_{\tilde{\chi}_1^0} > \approx 700$	no limit
$\tilde{t} \to t\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} = 0$	≈ 1300
	$m_{\tilde{\chi}_1^0} > \approx 600$	no limit
$\tilde{t} \to b\tilde{\chi}_1^\pm$	$m_{\tilde{\chi}_1^0} = 0$	≈ 1150
$(m_{\tilde{\chi}_1^\pm} = (m_{\tilde{t}} - m_{\tilde{\chi}_1^0})/2)$	$m_{\tilde{\chi}_1^0} > \approx 550$	no limit
$\tilde{t} \to Wb\tilde{\chi}_1^0$	$m_{\tilde{\chi}_1^0} < \approx 570$	≈ 700
$(m_W < m_{\tilde{t}} - m_{\tilde{\chi}^0} < m_t)$		
$\tilde{t} \to c\tilde{\chi}_1^0$	$m_{\tilde{t}} - m_{\tilde{\chi}_1^0} \approx 50$	≈ 630
	$m_{\tilde{t}} \approx m_{\tilde{\chi}_1^0}$	≈ 550
$\tilde{t} \to bff'\tilde{\chi}_1^0$	$m_{\tilde{t}} - m_{\tilde{\chi}_1^0} \approx 50$	≈ 650
	$m_{\tilde{t}} \approx m_{\tilde{\chi}_1^0}$	≈ 550
$(m_{\tilde{t}} - m_{\tilde{\chi}^0} < m_W)$		

In general, the variety of top squark decay chains in the phase space region where $\tilde{t} \to t\tilde{\chi}_1^0$ is kinematically forbidden represents a challenge for the experimental search program but more data and refined analyses in Run 2 have further improved the sensitivity in this difficult but important region of SUSY parameter space, and more is expected for future Runs of the LHC. It is also worth mentioning that precision SM measurements can provide important insights to such challenging regions. For instance, analyses of $t\bar{t}$ spin correlations can be used to set constraints on top squark masses close to the top-quark mass. ATLAS [115] excludes the mass region between 150 and 230 GeV for kinematically allowed values of the neutralino mass. CMS [116] results cover a similar mass range.

It should be noted that limits discussed in this section belong to different top and bottom squark decay channels, different sparticle mass hierarchies, and different simplified decay scenarios. Therefore, care must be taken when interpreting these limits in the context of more complete SUSY models.

89.7 Exclusion limits on squarks and gluinos in RPV scenarios

RPV gluino and squark decays are searched for in a number of final states, generally characterised by the presence of multiple leptons or jets and moderated or no missing transverse momentum. If the couplings are very small, sparticles might be long-lived and dedicated searches for non-prompt decays are reported in Section 89.10.

Searches in multilepton final states [117–121] set lower mass limits of 1 to 1.4 TeV, depending on neutralino mass and lepton flavor, on decays mediated by λ and λ' couplings, assuming prompt decays. Multijet final states have been used to search for fully hadronic gluino decays involving λ'' couplings, by CDF [122], ATLAS [88,123–126] and CMS [127–129]. Lower gluino mass limits range between 600 and 2000 GeV depending on neutralino mass and flavor content of the final state. More recently, ATLAS [130] searched in events characterised by high jet multiplicity, at least one isolated light lepton and either zero or at least three b-tagged jets, reaching as high as 2.4 TeV in gluino mass.

RPV production of single squarks via a λ'-type coupling has been studied at HERA. In such models, a lower limit on the squark mass of the order of 275 GeV has been set for electromagnetic-strength-like couplings $\lambda' = 0.3$ [131]. At the LHC, prompt [118, 121, 132] R-parity violating squark decays have been searched for with mass limits are very model-dependent.

Dedicated searches for RPV top squarks (at production and/or in decays) have been carried out in the past decades. Production of single top squarks has been searched for at LEP, HERA, and the Tevatron. For example, an analysis from the ZEUS collaboration [133] makes an interpretation of its search result assuming top squarks to be produced via a λ' coupling and decay either to $b\tilde{\chi}_1^\pm$ or R-parity-violating to a lepton and a jet. Limits are set on λ'_{131} as a function of the top squark mass in an MSSM framework with gaugino mass unification at the GUT scale. The search for top squark pair production in the context of RPV supersymmetry has now also become a focus point for searches at the LHC. CMS and ATLAS have performed several searches for top squarks using a variety of multilepton and/or multijet final states and Run 2 data. The λ'-mediated top squark decay $\tilde{t} \to b\ell$ has been studied

by ATLAS for prompt decays [134], and by ATLAS and CMS for non-prompt decays [135–137], setting limits up to $1.4 - 1.6$ TeV in simplified models for this mode. CMS also searched for the λ'-mediated decay $\tilde{t} \to b\ell qq$, setting lower stop mass limits of 890 GeV (e) or 1000 GeV (μ) [138]. The fully hadronic R-parity violating top squark decays $\tilde{t} \to bs$, $\tilde{t} \to ds$, and $\tilde{t} \to bd$, involving λ'', have been searched for by ATLAS [118, 124, 139–141], and CMS [142,143]. Other recent searches target top squarks decaying through cascades into several $b-$ and light-quarks, for example as in [144]. The most recent results set lower top squark mass limits up to 1.35 TeV in top-squark mass [130] if decays include top- and b-quarks [130] lower top squark mass limits are up to 1.35 TeV in top-squark mass. Constraints on masses up to 670 GeV are found if top squarks decays include top- and light-quarks [145].

RPV signatures are often similar to signatures of Stealth SUSY [146–148]. In these scenarios, squarks can decay to a quark and a chargino (neutralino), which can subsequently decay to a singlino $\tilde{S}$ and a $W^{\pm}$ (photon), with the $\tilde{S}$ decaying to two gluons and a soft gravitino $\tilde{G}$. A dedicated CMS search [149] excludes squark masses up to 1.05 TeV in the photon channel and up to 550 GeV in the charged lepton channel. Limits have also been placed on top squarks in stealth SUSY scenarios, where the top squark decays to a top quark, a gluon and a $\tilde{S}$, and the $\tilde{S}$ subsequently decays to a $\tilde{G}$ and two gluons. In such a scenario, top squark masses up to 870 GeV have been excluded [145].

89.8 Exclusion limits on the masses of charginos, neutralinos and sleptons in RPC scenarios

Charginos, neutralinos and sleptons are produced through electroweak interactions and their cross sections depend on the assumptions made for mass and mixing parameters.

Charginos and neutralinos carry no color charge and the mixing of the charged wino and higgsino states (for charginos), and the neutral bino, wino and higgsino states (for neutralinos), is determined by a limited number of parameters. For charginos these are the wino mass parameter M_2, the higgsino mass parameter μ, and $\tan\beta$, and for neutralinos these are the same parameters plus the bino mass parameter M_1. If one of the parameters M_1, M_2 or μ is substantially smaller than the others, the chargino/neutralino composition would be dominated by specific states, which are referred to as bino-like ($M_1 \ll M_2, \mu$), wino-like ($M_2 \ll M_1, \mu$), or higgsino-like ($\mu \ll M_1, M_2$). If gaugino mass unification at the GUT scale is assumed, a relation between M_1 and M_2 at the electroweak scale follows: $M_1 = 5/3 \tan^2\theta_W M_2 \approx 0.5 M_2$, with θ_W the weak mixing angle. The largest production rates at hadron machines are obtained when the LSP is bino-like and the lightest chargino and next-to-lightest neutralino are wino-like, forming an approximately mass degenerate SU(2) triplet. If the higgsino mass is much smaller than the gaugino masses, the two lightest neutralinos and the lightest chargino form an approximately mass degenerate Dirac SU(2) doublet, production rates are lower and the mass spectrum is compressed.

In models with slepton and gaugino mass unification at the GUT scale, the superpartner of the right-handed lepton, $\tilde{\ell}_{\rm R}$, is expected to be lighter than the left-handed one, $\tilde{\ell}_{\rm L}$. Cross sections depend on the L-R mixing which in turn depends on the mass of the fermion and other parameters. For tau sleptons there may be considerable mixing between the L and R states, leading to a significant mass difference between the lighter $\tilde{\tau}_1$ and the heavier $\tilde{\tau}_2$.

Fig. 89.7 [150, 151] (see also Ref. [72] for further details) shows typical production cross sections at hadron colliders for electroweakinos under various assumptions. For masses of several hundreds of GeV, they are at least two orders of magnitude smaller than for colored SUSY particles. Thanks to the large data samples collected at the LHC, the sensitivity of LEP and Tevatron searches for direct chargino/neutralino or slepton production has been surpassed in several regions of SUSY parameter space.

89.8.1 *Exclusion limits on chargino masses*

The lightest chargino $\tilde{\chi}_1^{\pm}$ is searched for either considering pair production, or through associated production of $\tilde{\chi}_1^{\pm}$ and the next-to-lightest neutralino, $\tilde{\chi}_2^0$, if they are assumed to be degenerate

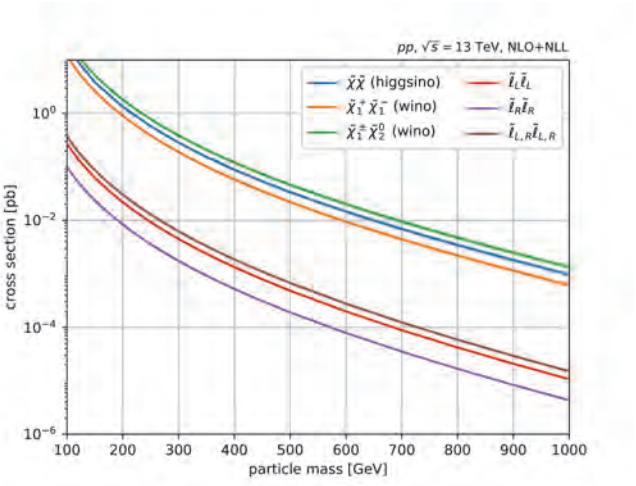

Figure 89.7: Cross sections for pair production of charginos, neutralinos and sleptons calculated for 13 TeV centre-of-mass energy at NLO plus next-to-leading-log (NLL) precision. Wino-like $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$ and $\tilde{\chi}_1^+\tilde{\chi}_1^-$ productions are calculated in a limit of mass-degenerate $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$, light bino $\tilde{\chi}_1^0$, and with all the other sparticles assumed to be heavy and decoupled. Higgsino-like cross sections assume mass-degenerate $\tilde{\chi}_1^{\pm}$, $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$. For slepton pair cross sections, left(right)-handed only or 50% mixed states are considered.

in mass. If kinematically allowed, two body decay modes such as $\tilde{\chi}^{\pm} \to \tilde{f}\bar{f}'$ (including $\ell\tilde{\nu}$ and $\tilde{\ell}\nu$) are dominant. If not, three body decays $\tilde{\chi}^{\pm} \to f\bar{f}'\tilde{\chi}_1^0$, mediated through virtual W bosons or sfermions, become dominant. If sfermions are heavy, the W mediation dominates, and $f\bar{f}'$ are distributed with branching fractions similar to W decay products (barring phase space effects for small mass gaps between $\tilde{\chi}^{\pm}$ and $\tilde{\chi}^0$). If, on the other hand, sleptons are light enough to play a significant role in the decay, leptonic final states will be enhanced.

At LEP, $\tilde{\chi}_1^+\tilde{\chi}_1^-$ is the dominant production process. Charginos have been searched for in fully-hadronic, semi-leptonic and fully leptonic decay modes [152, 153]. A general lower limit on the lightest chargino mass of 103.5 GeV is derived, except in corners of phase space with low electron sneutrino mass, where destructive interference in chargino production, or two-body decay modes, play a role. The limit is also affected if the mass difference between $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0$ is small; dedicated searches for such scenarios set a lower limit of 92 GeV.

At the Tevatron, charginos have been searched for via associated production of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0$ [154, 155]. Decay modes involving multilepton final states provide the best discrimination against the large multijet background. Analyses have looked for at least three charged isolated leptons, for two leptons with missing transverse momentum, or for two leptons with the same charge. Depending on the $(\tilde{\chi}_1^{\pm} - \tilde{\chi}_1^0)$ and/or $(\tilde{\chi}_2^0 - \tilde{\chi}_1^0)$ mass differences, leptons may have soft transverse momentum.

At the LHC, the search strategy is similar to that at the Tevatron but it also exploits the large datasets collected to target missing momentum and fully-hadronic final states and consider $\tilde{\chi}_1^+\tilde{\chi}_1^-$ production only i.e. releasing the assumption of $\tilde{\chi}_1^{\pm}, \tilde{\chi}_2^0$ mass degeneracy. Furthermore, compressed SUSY spectra are searched for considering low-momentum leptons recoiling against an ISR jet.

Chargino pair production is searched for in the dilepton plus missing momentum final state. In a simplified model interpretation of the results where only the $\tilde{\chi}_1^+\tilde{\chi}_1^-$ process is considered and assuming mediation of the chargino decay by light sleptons ($\tilde{e}$ and $\tilde{\mu}$), ATLAS [156] and CMS [157] set limits on the chargino mass up to 1 TeV for massless LSPs, but no limits on the chargino mass can be set for $\tilde{\chi}_1^0$ heavier than 480 GeV. Limits are fairly

robust against variation of the slepton mass, unless the mass gap between sparticles becomes small enough that the charged lepton has a too low-momentum to be reconstructed. For decays mediated through $\tilde{\tau}$ or $\tilde{\nu}_\tau$, limits of 630 GeV are set by ATLAS [158] for LSPs not heavier than 200 GeV. The CMS experiment provides similar limits [159].

In case slepton masses are higher than the mass of the chargino, searches are performed for charginos decaying via a W boson. ATLAS sets limits on this kind of simplified models [156] for pure-wino charginos: masses below 420 GeV are excluded for massless LSPs, but no limits are set for LSPs heavier than 120 GeV. Further extension of the sensitivity in the high-mass region is achieved by ATLAS [160] and CMS [161] exploiting the large branching ratio of fully-hadronic final states and the identification of boosted W bosons through large-radius jets and jet substructure information. Considering only wino-like chargino pair production in case of a massless LSP, ATLAS excludes a region between 630 GeV and 760 GeV, while CMS excludes between 290 GeV and 670 GeV. No limits are set for LSP masses above 200 GeV.

Several final states characterised by the presence of missing transverse momentum are studied to set limits on the chargino mass through $\tilde{\chi}_1^\pm \tilde{\chi}_2^0$ associated production. Usually, wino-like $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ and bino-like $\tilde{\chi}_1^0$ are assumed with $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, leaving $m_{\tilde{\chi}_1^\pm}$ and $m_{\tilde{\chi}_1^0}$ free. Again, the branching fraction of leptonic final states is determined by the slepton masses. If the decay is predominantly mediated by a light $\tilde{\ell}_\mathrm{L}$, i.e. $\tilde{\ell}_\mathrm{R}$ is assumed to be heavy, the three charged-lepton flavors will be produced in equal amounts, and a multi-lepton signature is favored. It is assumed that $\tilde{\ell}_\mathrm{L}$ and sneutrino masses are equal, and diagrams with sneutrinos are included. In this scenario, ATLAS [162] and CMS [163] exclude chargino masses below 1450 GeV for massless LSPs; no limits are set for LSP masses above 1 TeV. If the decay is dominated by a light $\tilde{\ell}_\mathrm{R}$, the chargino cannot be a pure wino but needs to have a large higgsino component, preferring the decays to tau leptons. Limits are set in various scenarios. If, like for $\tilde{\ell}_\mathrm{L}$, a flavor-democratic scenario is assumed (τ-enriched scenario), CMS sets limits of 1150 GeV on the chargino mass for massless LSPs, but under the assumption that both $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ decay leads to tau leptons in the final state (τ-dominated scenario), the chargino mass limit deteriorates to 970 GeV for massless LSPs [163]. ATLAS assumes a simplified model in which staus are significantly lighter than the other sleptons in order to search for a similar multi-tau final state, and sets a lower limit on the chargino mass of 760 GeV in this model [158].

If sleptons are heavy, the chargino is assumed to decay to a W boson plus LSP, and the $\tilde{\chi}_2^0$ into Z plus LSP or H plus LSP. Searches for the WZ channel exploit events with either two same-sign leptons or three leptons, or with no leptons (all-hadronic). ATLAS searches in events with three leptons and missing momentum and wino-like chargino masses below 640 GeV are excluded for massless LSPs [164]. Limits are reduced in case of higgsino-like scenarios, with exclusion down to 210 GeV. Searches exploiting all-hadronic final states where boosted, fully-hadronically decaying W, Z and Higgs boson candidates are identified using dedicated algorithm are carried out by ATLAS [160] and CMS [161]. ATLAS excludes wino-like $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ masses between 440 GeV and 960 GeV for an LSP mass below 300 GeV. Similar constraints are obtained by CMS.

Interpretations are also provided in a scenario where the $\tilde{\chi}_2^0$ does not decay exclusively into Z plus LSP. CMS [163] excludes chargino masses below 650 GeV for massless LSPs, using events with two leptons of the same sign, or with three or more leptons. No constraints are set for $\tilde{\chi}_1^0$ masses above 300 GeV. Similarly to ATLAS, limits are pushed further utilising fully-hadronic final states [161].

If $\tilde{\chi}_2^0$ decays through a Higgs boson with $m_H = 125$ GeV, searches targeting the WH channel are relevant. Assuming SM-like Higgs decay modes and branching fractions, Higgs bosons in the final state are identified by either two jets originating from bottom quarks ($h \to b\bar{b}$), two photons ($h \to \gamma\gamma$), or leptons from the WW, ZZ or $\tau\tau$ decay modes. Searches exploiting the presence of b-jets are most sensitive in the high-mass chargino region, while analyses targeting photon pair or leptonic decays of the Higgs boson provide the best sensitivity in the region of low masses. CMS [165] sets lower limits on the chargino mass up to 820 GeV for massless LSPs, but vanish for LSP masses above 350 GeV using events with at least one lepton and missing transverse momentum in the final state. Similar sensitivity is achieved by the ATLAS analyses [166–168].

Additional constraints on the chargino mass are placed exploiting all-hadronic analyses. A wino-like (higgsino-like) chargino with mass up to 1060 (900) GeV is excluded by ATLAS [160] when the LSP mass is below 400 (240) GeV and the mass splitting is larger than 400 (450) GeV. CMS [161] excludes wino-like charginos with mass up to 970 GeV for massless LSP.

In both the wino region (a characteristic of anomaly-mediated SUSY breaking models) and the higgsino region of the MSSM, the mass splitting between $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ is small. The chargino decay products are very soft and may escape detection. These compressed spectra are hard to detect, and have triggered dedicated search strategies. ATLAS [169] and CMS [170] have performed searches for charginos and neutralinos in a compressed mass spectrum using initial state radiation and two or three low-momentum (soft) leptons. For wino-like charginos, assuming degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, exclusion contours in the chargino-mass versus $\Delta m(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0)$ plane are derived. As an example, such charginos are excluded by CMS (ATLAS) below 280 (240) GeV for $\Delta m(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0) = 10$ GeV. Considering the higgsino model, the masses probed by CMS reach up to 215 GeV for a mass difference of 7.5 GeV and 150 GeV in the highly compressed region with a mass difference of 3 GeV. CMS has also searched for chargino-pair production through vector-boson-fusion [171], also targeting compressed mass spectra. Assuming degenerate $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$, charginos with a mass below 112 GeV are excluded for $\Delta m(\tilde{\chi}_1^\pm - \tilde{\chi}_1^0) = 1$ GeV. CMS has published further searches for such compressed spectra with a soft tau lepton [172].

89.8.2 *Exclusion limits on neutralino masses*

In a considerable part of the MSSM parameter space, and in particular when demanding that the LSP carries no electric or color charge, the lightest neutralino $\tilde{\chi}_1^0$ is the LSP. If R-parity is conserved, such a $\tilde{\chi}_1^0$ is stable. Since it is weakly interacting, it will typically escape detectors unseen. Limits on the invisible width of the Z boson apply to neutralinos with a mass below 45.5 GeV, but depend on the Z-neutralino coupling. Such a coupling could be small or even absent; in such a scenario there is no general lower limit on the mass of the lightest neutralino [173]. In models with gaugino mass unification and sfermion mass unification at the GUT scale, a lower limit on the neutralino mass is derived from limits from direct searches, notably for charginos and sleptons, and amounts to 47 GeV [174]. Assuming a constrained model like the CMSSM, this limit increases to 50 GeV at LEP; however the strong constraints now set by the LHC increase such CMSSM-derived $\tilde{\chi}_1^0$ mass limits to well above a few hundred GeV (the latest reinterpretation only uses Run 1 data and indicates 200 GeV [175–177]).

In gauge-mediated SUSY breaking models (GMSB), the LSP is typically a gravitino, and the phenomenology is determined by the nature of the next-to-lightest supersymmetric particle (NLSP). A NLSP neutralino will decay to a gravitino and a SM particle whose nature is determined by the neutralino composition. Final states with two high p_T photons and missing momentum are searched for, and interpreted in gauge mediation models with bino-like neutralinos [178–183].

Assuming the production of at least two neutralinos per event, neutralinos with large non-bino components can also be searched for by their decay in final states with missing momentum plus any two bosons out of the collection γ, Z, H. A number of searches at the LHC have tried to cover the rich phenomenology predicted by the general gauge mediation model (GGM) where $\tilde{\chi}_1^0$ might decay with various BR in the Z and H decay modes [90,117,160,167,181,184–193]. As an example, strong constraints for decay modes involving Z and H bosons arise from

full-hadronic searches on higgsino-like scenarios: ATLAS [160] excludes higgsino production with decays into a massless gravitino LSP in a mass range between 450 (500) GeV and 940 (850) GeV assuming BR = 1 (0.5) for the Z plus gravitino decay mode. Assuming only H plus gravitino decays, CMS [194] excludes a higgsino mass range between 175 GeV and 1025 GeV.

Heavier neutralinos, in particular $\tilde{\chi}_2^0$, have been searched for in their decays to the lightest neutralino plus a γ, a Z boson or a Higgs boson. Limits on electroweak production of $\tilde{\chi}_2^0$ plus $\tilde{\chi}_1^\pm$ from all-hadronic, same-sign dilepton and trilepton analyses have been discussed in the section on charginos; the assumption of equal mass of $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ make the limits on chargino masses apply to $\tilde{\chi}_2^0$ as well. Multilepton analyses have also been used to set limits on $\tilde{\chi}_2^0\tilde{\chi}_3^0$ production; assuming equal mass and decay through light sleptons, limits are set up to 680 GeV for massless LSPs [195]. Again, compressed spectra with small mass differences between the heavier neutralinos and the LSP form the most challenging region.

In $\tilde{\chi}_2^0$ decays to $\tilde{\chi}_1^0$ and a lepton pair, the lepton pair invariant mass distribution may show a structure that can be used to measure the $\tilde{\chi}_2^0 - \tilde{\chi}_1^0$ mass difference in case of a signal [38]. This structure, however, can also be used in the search strategy itself, as demonstrated by ATLAS [196,197] and CMS [90,198].

Fig. 89.8 summarizes some of the most recent results from ATLAS and CMS for chargino pair or chargino and next-to-lightest neutralino pair productions comparing results obtained with various assumptions. The limits on weak gauginos in simplified models are also summarized in Table 89.3. Only results for promptly decaying charginos and neutralinos are included: limits from searches focusing on long-lived particle scenarios are reported in Section 89.10.

Interpretations of the search results outside simplified models, such as in the phenomenological MSSM [199–204], show that the simplified model limits can translate into accurate constraints but must also be interpreted with care. Electroweak gauginos in models that are compatible with the relic density of dark matter in the Universe, for example, have particularly tuned mixing parameters and mass spectra, which are not always captured by the simplified models used.

89.8.3 *Exclusion limits on slepton masses*

The most model-independent searches for selectrons, smuons and staus originate from the LEP experiments [205]. Smuon production only takes place via s-channel γ^*/Z exchange. Search results are often quoted for $\tilde{\mu}_\mathrm{R}$, since it is typically lighter than $\tilde{\mu}_\mathrm{L}$ and has a weaker coupling to the Z boson; limits are therefore conservative. Decays are expected to be dominated by $\tilde{\mu}_\mathrm{R} \to \mu\tilde{\chi}_1^0$, leading to two non-back-to-back muons and missing momentum. Slepton mass limits are calculated in the MSSM under the assumption of gaugino mass unification at the GUT scale, and depend on the mass difference between the smuon and $\tilde{\chi}_1^0$. A $\tilde{\mu}_\mathrm{R}$ with a mass below 94 GeV is excluded for $m_{\tilde{\mu}_\mathrm{R}} - m_{\tilde{\chi}_1^0} > 10$ GeV. The selectron case is similar to the smuon case, except that an additional production mechanism is provided by t-channel neutralino exchange. The $\tilde{e}_\mathrm{R}$ lower mass limit is 100 GeV for $m_{\tilde{\chi}_1^0} < 85$ GeV. Due to the t-channel neutralino exchange, $\tilde{e}_\mathrm{R}\tilde{e}_\mathrm{L}$ pair production was possible at LEP, and a lower limit of 73 GeV was set on the selectron mass regardless of the neutralino mass by scanning over MSSM parameter space [206]. The potentially large mixing between $\tilde{\tau}_\mathrm{L}$ and $\tilde{\tau}_\mathrm{R}$ not only makes the $\tilde{\tau}_1$ light, but can also make its coupling to the Z boson small. LEP lower limits on the $\tilde{\tau}$ mass range between 87 and 93 GeV depending on the $\tilde{\chi}_1^0$ mass, for $m_{\tilde{\tau}} - m_{\tilde{\chi}_1^0} > 7$ GeV [205].

At the LHC, pair production of sleptons is not only heavily suppressed with respect to pair production of colored SUSY particles but the cross section is also almost two orders of magnitude smaller than the one of pair production of charginos and neutralinos. With the full data sets of Run 1 and Run 2, however, ATLAS and CMS have surpassed the sensitivity of the LEP analyses under certain assumptions.

Table 89.3: Summary of weak gaugino mass limits in simplified models, assuming R-parity conservation. Masses in the table are provided in GeV. Further details about assumptions and corresponding analyses are discussed in the text. Details on constraints for compressed scenarios from soft-lepton searches are not represented in the table.

Assumption	m_χ
$\tilde{\chi}_1^\pm$, all $\Delta m(\tilde{\chi}_1^\pm, \tilde{\chi}_1^0)$	> 92
$\tilde{\chi}_1^\pm$ $\Delta m > 5$, $m_{\tilde{\nu}} > 300$	> 103.5
$\tilde{\chi}_1^\pm$, $m_{(\tilde{\ell},\tilde{\nu})} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 1000
$\tilde{\chi}_1^\pm$, $m_{\tilde{\chi}_1^0} > 480$	no LHC limit
$\tilde{\chi}_1^\pm$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 420 and $290 - 760$
$\tilde{\chi}_1^\pm$, $m_{\tilde{\chi}_1^0} > 120$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}_\mathrm{L}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 1450
$m_{\tilde{\chi}_1^0} > 1000$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}_\mathrm{R}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	flavor-democratic
$m_{\tilde{\chi}_1^0} \approx 0$	> 1150
$m_{\tilde{\chi}_1^0} > 700$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\tau}} = (m_{\tilde{\chi}_1^\pm} + m_{\tilde{\chi}_1^0})/2$	$\tilde{\tau}$-dominated
$m_{\tilde{\chi}_1^0} \approx 0$	> 970
$m_{\tilde{\chi}_1^0} > 450$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$, BF$(WZ) = 1$	
$m_{\tilde{\chi}_1^0} \approx 0$	> 960
$m_{\tilde{\chi}_1^0} > 300$	no LHC limit
$m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0}$, $m_{\tilde{\ell}} > m_{\tilde{\chi}_1^\pm}$, BF$(WH) = 1$	
$m_{\tilde{\chi}_1^0} \approx 0$, wino-like $\tilde{\chi}_1^\pm$	> 1060
$m_{\tilde{\chi}_1^0} \approx 0$, higgsino-like $\tilde{\chi}_1^\pm$	> 900
$m_{\tilde{\chi}_1^0} > 400(240)$	no LHC limit wino(higgsino)-like

ATLAS and CMS have searched for direct production of selectron pairs and smuon pairs at the LHC, with each slepton decaying to its corresponding SM partner lepton and the $\tilde{\chi}_1^0$ LSP. In simplified models, ATLAS [156] and CMS [198] set lower mass limits on sleptons of 700 GeV for degenerate $\tilde{\ell}_\mathrm{L}$ and $\tilde{\ell}_\mathrm{R}$, for a massless $\tilde{\chi}_1^0$ and assuming equal selectron and smuon masses, as shown in Fig. 89.9. The limits deteriorate with increasing $\tilde{\chi}_1^0$ mass due to decreasing missing momentum and lepton momentum. As a consequence, no limits are set for $\tilde{\chi}_1^0$ masses above 400 GeV. Limits are also derived without the assumption of slepton mass degeneracy [156,207]. A dedicated search for sleptons with small mass difference between $\tilde{\ell}$ and $\tilde{\chi}_1^0$ is performed by ATLAS [208] demanding the presence of ISR jets. Although no sensitivity is achieved for intermediate mass differences between the slepton and the LSP, slepton masses up to 260 GeV are excluded for slepton-LSP mass differences of 10-20 GeV.

ATLAS and CMS have also searched for $\tilde{\tau}$-pair production. In simplified models, ATLAS excludes $\tilde{\tau}$ masses between 120 and 390 GeV assuming light $\tilde{\chi}_1^0$, combining the production of degenerate left- and right-handed $\tilde{\tau}$s [209]. The CMS analysis [210] covers lower masses and closes the mass gap with LEP. A recent update from CMS [211] exclude purely left-handed $\tilde{\tau}$s with masses between 115 and 340 GeV for massless LSP.

In gauge-mediated SUSY breaking models, sleptons can be (co-)NLSPs, *i.e.*, the next-to-lightest SUSY particles and almost degenerate in mass, decaying to a lepton and a gravitino. This decay can either be prompt, or the slepton can have a non-zero lifetime. Combining several analyses, lower mass limits on $\tilde{\mu}_\mathrm{R}$ of 96.3 GeV

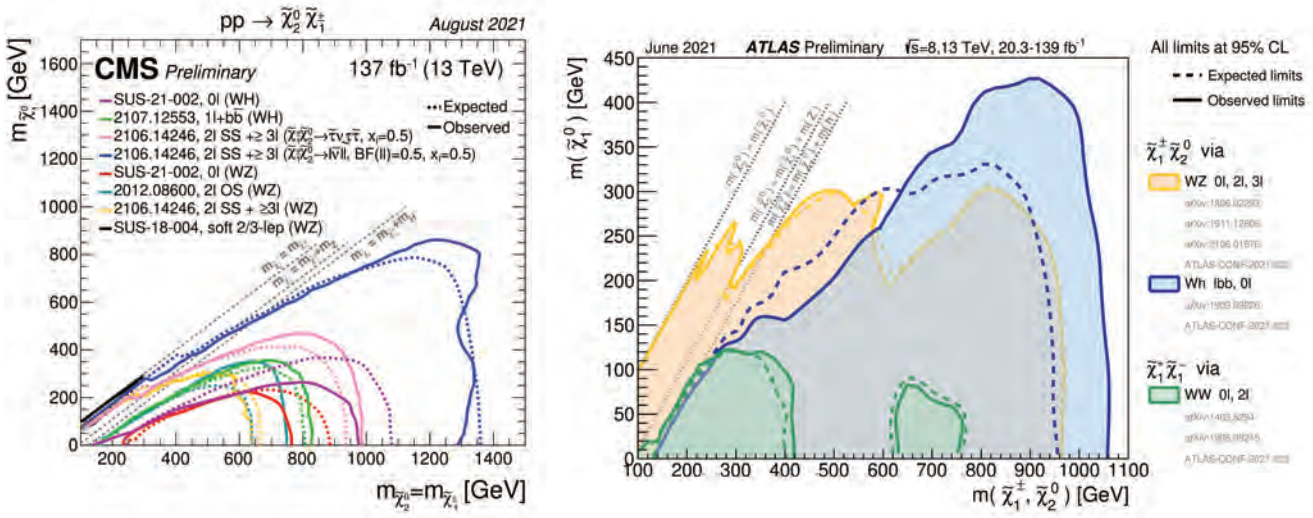

Figure 89.8: LHC exclusion limits on chargino and neutralino masses in a number of simplified models. Left: CMS limits on chargino and neutralino masses for pair production of charginos, pair production of heavier neutralinos, or pair production of chargino and neutralino, under a variety of assumptions including light sleptons mediating the decays. Right: ATLAS limits on chargino and neutralino masses for pair production of chargino and neutralino, under the assumption of decoupled sleptons, and chargino/neutralino decay through on- or off-shell W and Z or H.

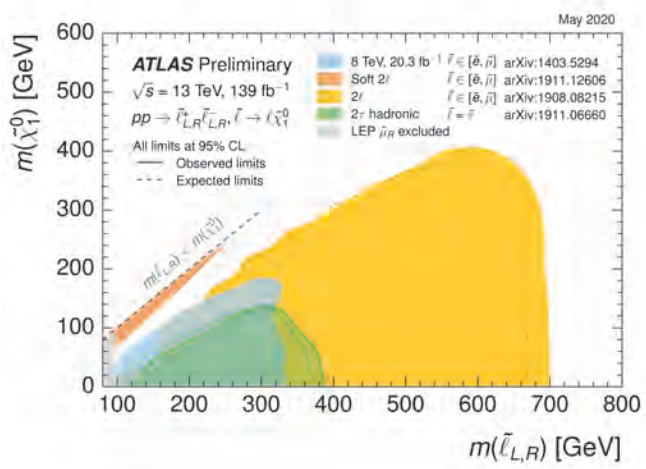

Figure 89.9: LHC exclusion limits on slepton (selectron and smuon) masses, assuming equal masses of selectrons and smuons, degeneracy of $\tilde{\ell}_L$ and $\tilde{\ell}_R$, and a 100% branching fraction for $\tilde{\ell} \rightarrow \ell\tilde{\chi}_1^0$.

and on $\tilde{e}_R$ of 66 GeV are set for all slepton lifetimes at LEP [212]. In a considerable part of parameter space in these models, the $\tilde{\tau}$ is the NLSP. The LEP experiments have set lower limits on the mass of such a $\tilde{\tau}$ between 87 and 97 GeV, depending on the $\tilde{\tau}$ lifetime. ATLAS and CMS have searched for final states with τs, jets and missing transverse momentum, and have interpreted the results in GMSB models setting limits on the model parameters [213, 214]. CMS has interpreted a multilepton analysis in terms of limits on gauge mediation models with slepton NLSP [215]. CDF has put limits on gauge mediation models at high $\tan\beta$ and slepton NLSP using an analysis searching for like-charge light leptons and taus [216].

The invisible width of the Z boson puts a lower limit on the sneutrino mass of about 45 GeV. Tighter limits are derived from other searches, notably for gauginos and sleptons, under the assumption of gaugino and sfermion mass universality at the GUT scale, and amount to approximately 94 GeV in the MSSM [217].

The limits on sleptons in simplified models are summarized in Table 89.4.

Table 89.4: Summary of slepton mass limits from LEP and LHC, assuming R-parity conservation and 100% branching fraction for $\tilde{\ell} \rightarrow \ell\tilde{\chi}_1^0$. Masses in this table are provided in GeV.

Assumption	$m_{\tilde{\ell}}$
$\tilde{\mu}_R$, $\Delta m(\tilde{\mu}_R, \tilde{\chi}_1^0) > 10$	> 94
$\tilde{e}_R$, $\Delta m(\tilde{e}_R, \tilde{\chi}_1^0) > 10$	> 94
$\tilde{e}_R$, any Δm	> 73
$\tilde{\tau}_R$, $\Delta m(\tilde{\tau}_R, \tilde{\chi}_1^0) > 7$	> 87
$\tilde{\nu}_e$, $\Delta m(\tilde{e}_R, \tilde{\chi}_1^0) > 10$	> 94
$m_{\tilde{e}_{L,R}} = m_{\tilde{\mu}_{L,R}}$, $m_{\tilde{\chi}_1^0} \approx 0$	> 700
$m_{\tilde{\chi}_1^0} >\approx 400$	no LHC limit
$m_{\tilde{\tau}_L} = m_{\tilde{\tau}_R}$, $m_{\tilde{\chi}_1^0} \approx 0$	> 390
$m_{\tilde{\chi}_1^0} >\approx 130$	no LHC limit

89.9 Exclusion limits on the masses of charginos, neutralinos and sleptons in RPV scenarios

In models with R-parity violation, the lightest neutralino can decay even if it is the lightest supersymmetric particle. If the decay involves a non-zero λ coupling, the final state will be a multi-lepton one. Searches for events with four or more isolated charged leptons by ATLAS [117] and CMS [121] are interpreted in such models.

Various searches, including searches for multi-lepton and lepton plus jets events, are interpreted in a model with R-parity violating neutralino decays involving a non-zero λ' coupling [118, 126, 218, 219]. Neutralino decays involving non-zero λ'' lead to fully hadronic final states, and searches for multi-jet events and jet-pair resonances are used to set limits, typically on the production of colored particles like top squarks or gluinos, which are assumed to be the primary produced sparticles in these interpretations, as discussed earlier 89.7. For instance, the ATLAS search [130] in events with one lepton and high jet multiplicity excludes up to 320(365) GeV in higgsino (wino) masses. Recent searches [220] also set limits on the production of charginos and neutralinos for a Minimal SUSY model with an approximate $B - L$ symmetry. Charginos and neutralinos with masses between 100 GeV and 1100 GeV are excluded depending on the assumed decay BR into a lepton plus a W, Z or H boson.

Limits also exist on sleptons in R-parity violating models, both from LEP and the Tevatron experiments. From LEP, lower limits

on $\tilde{\mu}_R$ and $\tilde{e}_R$ masses in such models are 97 GeV, and the limits on the stau mass are very close: 96 GeV [221]. CMS has searched for resonant smuon production in a modified CMSSM scenario [222], putting limits on λ'_{211} as a function of $m_0, m_{1/2}$.

Production of pairs of sneutrinos in R-parity violating models has been searched for at LEP [221]. Assuming fully leptonic decays via λ-type couplings, lower mass limits between 85 and 100 GeV are set. At the Tevatron [223, 224] and at the LHC [222, 225–227], searches have focused on scenarios with resonant production of a sneutrino, decaying to $e\mu$, $\mu\tau$ and $e\tau$ final states. No signal has been seen, and limits have been set on sneutrino masses as a function of the value of relevant RPV couplings. As an example, the LHC experiments exclude a resonant tau sneutrino with a mass below 2.3 TeV for $\lambda_{312} = \lambda_{321} > 0.07$ and $\lambda'_{311} > 0.11$.

89.10 Exclusion limits on long-lived sparticles

Long-lived sparticles arise in many different SUSY models. In particular in co-annihilation scenarios, where the NLSP and LSP are nearly mass-degenerate, this is rather common in order to obtain the correct Dark Matter relic density. Prominent examples are scenarios featuring stau co-annihilation, or models of SUSY breaking, e.g. minimal anomaly-mediated SUSY breaking (AMSB), in which the appropriate Dark Matter density is obtained by co-annihilation of the LSP with an almost degenerate long-lived wino. However, in general, other sparticles can also be long-lived and it is desirable to establish a comprehensive search program for these special long-lived cases, which lead to distinct experimental search signatures. Searches for events with a displaced hadronic vertex, with or without a matched lepton, are for instance interpreted in a model with R-parity violating neutralino decays involving a non-zero λ' coupling [219]. Other signatures interpreted in terms of SUSY models include disappearing tracks, identification of tracks with atypical properties or unusual ionization, small and localized deposits of energy inside of the calorimeters without associated tracks, or stopped particles that decay out of time with collisions. Some examples are reported below.

Past experiments have performed dedicated searches for long-lived SUSY signatures, but given the absence of any experimental evidence for SUSY so far, more effort and focus has gone into such searches at the LHC recently.

If the decay of gluinos is suppressed, for example if squark masses are high, gluinos may live longer than typical hadronization times. It is expected that such gluinos will hadronize to long-living strongly interacting particles known as R-hadrons. In particular, if the suppression of the gluino decay is strong, as in the case that the squark masses are much higher than the TeV scale, these R-hadrons can be (semi-)stable in collider timescales. Searches for such R-hadrons exploit the typical signature of stable charged massive particles in the detector. R-hadrons decaying in the detector are searched for using dE/dx measurements and searches for displaced vertices. As shown in the left plot of Fig. 89.10, the ATLAS experiment excludes semi-stable gluino R-hadrons with masses below $1.9 - 2.3$ TeV for all lifetimes in a simplified model where such gluinos always form R-hadrons, and decay into jets and a light neutralino, by combining a number of analyses [124, 228–230]. A combination of CMS searches for long-lived particles, as shown in Fig. 89.11, reaches similar limits [231–235].

Alternatively, since such R-hadrons are strongly interacting, they may be stopped in the calorimeter or in other material, and decay later into energetic jets. These decays are searched for by identifying the jets [236–238] or muons [238] outside the time window associated with bunch-bunch collisions. As shown in Fig. 89.11, the CMS collaboration sets limits on such stopped R-hadrons over 13 orders of magnitude in gluino lifetime, up to masses of 1390 GeV [238]. Recent results from ATLAS [239] sets constraint on the mass of gluino R-hadrons using large out-of-time energy deposits in the calorimeters. Also in this case, masses of up to 1.4 TeV are excluded for gluino lifetimes of $10^{-5} - 10^{3}$ s.

Top squarks can also be long-lived and hadronize to a R-hadron, for example in the scenario where the top squark is the next-to-lightest SUSY particle (NLSP), with a small mass difference to the LSP. Searches for massive stable charged particles are sensitive to such top squarks. Tevatron limits are approximately $m_{\tilde{t}} > 300$ GeV [240, 241]. ATLAS sets a limit of 1340 GeV on such top squarks [229], the CMS limits are comparable [233]. Intermediate lifetimes of top squarks decaying through RPV coupling into a quark and a lepton are also targeted by ATLAS and CMS. Limits on top squarks decaying into a quark and a muon are set by ATLAS [242] using events that pass a muon or missing-transverse-momentum trigger and contain a displaced muon track and a displaced vertex. Masses up to 1.7 TeV are excluded for a lifetime of 0.1 ns, and masses below 1.3 TeV are excluded for lifetimes between 0.01 ns and 30 ns. CMS [243] utilizes events with two leptons with transverse impact parameter values between 0.01 and 10 cm not required to form a common vertex to exclude top squarks with masses between 100 and at least 460 GeV for $0.01 < c\tau_0 < 1000$ cm, where $c\tau_0$ is the proper decay length.

In addition to colored sparticles, sparticles like charginos may also be long-lived, especially in scenarios with compressed mass spectra. Charginos decaying in the detectors away from the primary vertex could lead to signatures such as kinked-tracks, or apparently disappearing tracks, since, for example, the pion in $\tilde{\chi}_1^{\pm} \rightarrow \pi^{\pm}\tilde{\chi}_1^0$ might be too soft to be reconstructed. At the LHC, searches have been performed for such disappearing tracks, and interpreted within anomaly-mediated SUSY breaking models [244–247]. The right plot of Fig. 89.10 shows constraints for different ATLAS searches on the chargino mass-vs-lifetime plane for an AMSB model ($\tan\beta = 5$, $\mu > 0$) in which a wino-like $\tilde{\chi}^{\pm}$ decays to a soft pion and an almost mass-degenerated wino-like $\tilde{\chi}_1^0$ [229, 230, 245–247]. For a similar model, CMS excludes $c\tau$ values between 0.15 and 18 m for a chargino mass of 505 GeV [244], see Fig. 89.11. The most recent ATLAS search [247] provides constraints also for higgsino-like models. Charginos with a lifetime longer than the time needed to pass through the detector appear as charged stable massive particles. Limits have been derived by the LEP experiments [248], by D0 at the Tevatron [241], and by the LHC experiments [229, 249], and such charginos with mass below 1090 GeV are excluded.

In gauge mediation models, NLSP neutralino decays need not be prompt, and experiments have searched for late decays with photons in the final state. CDF has searched for delayed $\tilde{\chi}_1^0 \rightarrow \gamma\tilde{G}$ decays using the timing of photon signals in the calorimeter [250]. CMS has used the same technique at the LHC [251]. Results are given as exclusion contours in the neutralino mass versus lifetime plane, and for example in a GMSB model with a neutralino mass of 300 GeV, $c\tau$ values between 10 and 2000 cm are excluded [251]. D0 has looked at the direction of showers in the electromagnetic calorimeter with a similar goal [252], and ATLAS has searched for photon candidates that do not point back to the primary vertex, as well as for delayed photons [253].

Charged slepton decays may be kinematically suppressed, for example in the scenario of a NLSP slepton with a very small mass difference to the LSP. Such a slepton may appear to be a stable charged massive particle. Interpretation of searches at LEP for such signatures within GMSB models with a stau NLSP or slepton co-NLSP exclude masses up to 99 GeV [248]. Searches for stable charged particles at the Tevatron [240, 241] and at the LHC [229, 233] are also interpreted in terms of limits on stable charged sleptons. The limits obtained at the LHC exclude stable staus with masses below 430 GeV when produced directly in pairs, and below 660 GeV when staus are produced both directly and indirectly in the decay of other particles in a GMSB model. Recent results from ATLAS and CMS set constraints on long-lived charged slepton with intermediate lifetimes. ATLAS searches for charged leptons with large impact parameters and exclude selectron, smuon and stau masses up to 720 GeV, 680 GeV, and 340 GeV, respectively, in case of lifetimes of 0.1 ns. CMS [211] targets long-lived stau with $c\tau$ of about 0.1 mm excluding masses between 115 and 220 GeV for the case that the LSP is nearly massless.

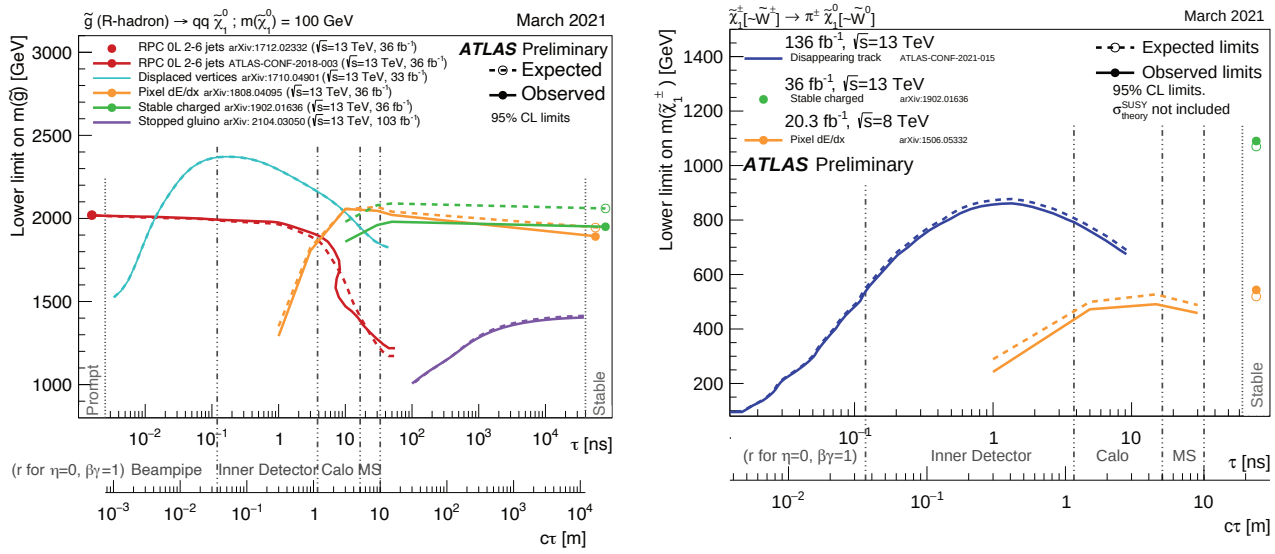

Figure 89.10: Limits at 95% C.L. on the gluino mass in R-hadron models (left), and on the chargino mass in a model where the wino-like chargino is almost degenerate with the LSP (right), as a function of gluino or chargino lifetime, as obtained by ATLAS.

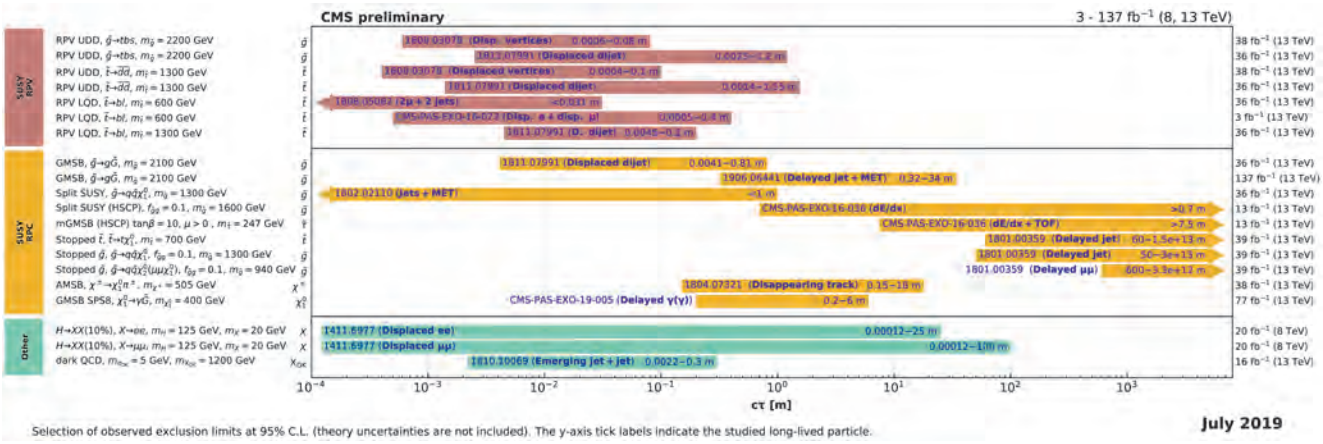

Figure 89.11: Excluded regions, at 95% C.L., in the lifetimes of long-lived particles in several models, as obtained by CMS.

89.11 Global interpretations

Apart from the interpretation of direct searches for sparticle production at colliders in terms of limits on masses of individual SUSY particles, model-dependent interpretations of allowed SUSY parameter space are derived from global SUSY fits. Typically these fits combine the results from collider experiments with indirect constraints on SUSY as obtained from low-energy experiments, flavor physics, high-precision electroweak results, and astrophysical data.

In the pre-LHC era these fits were mainly dominated by indirect constraints. Even for very constrained models like the CMSSM, the allowed parameter space, in terms of squark and gluino masses, ranged from several hundreds of GeV to a few TeV. Furthermore, these global fits indicated that squarks and gluino masses in the range of 500 to 1000 GeV were the preferred region of parameter space, although values as high as a few TeV were allowed with lower probabilities [254–261].

With ATLAS and CMS now probing mass scales around 1 TeV and beyond, the importance of the direct searches for global analyses of allowed SUSY parameter space has increased. For example, imposing the new experimental limits on constrained supergravity models pushes the most likely values of first generation squark and gluino masses significantly beyond 2 TeV, typically resulting in overall values of fit quality much worse than those in the pre-LHC era [175–177, 202, 262–269]. The measured value of m_h pushes the sparticle masses upwards. Although these constrained models are not yet ruled out, the extended experimental limits impose very tight constraints on the allowed parameter space.

For this reason, the emphasis of global SUSY fits has shifted towards less-constrained SUSY models. Interpretations in the pMSSM [200–204, 249, 262] as well as in simplified models, have been useful to generalize SUSY searches, for example to redesign experimental analyses in order to increase their sensitivity for compressed spectra, where the mass of the LSP is much closer to squark and gluino masses than predicted by the CMSSM. As shown in Table 89.1, for neutralino masses above $0.5 - 1$ TeV the current set of ATLAS and CMS searches, interpreted in simplified models, cannot exclude the existence of squarks or gluinos with masses only marginally above the neutralino mass. However, as these exclusion limits are defined in the context of simplified models, they are only valid for the assumptions in which these models are defined.

As an alternative approach, both ATLAS [200] and CMS [201] have performed an analysis of the impact of their searches on the parameter space of the pMSSM. Fig. 89.12 shows graphically the LHC exclusion power in the pMSSM based on searches performed at $\sqrt{s} = 7$ and 8 TeV. The plot on the left shows the survival probability in the gluino-neutralino mass plane, which is a measure of the parameter space that remains after inclusion of the relevant CMS search results. As can be seen, gluino masses below about 1.2 TeV are almost fully excluded. This result agrees well with the typical exclusion obtained at 8 TeV in simplified mod-

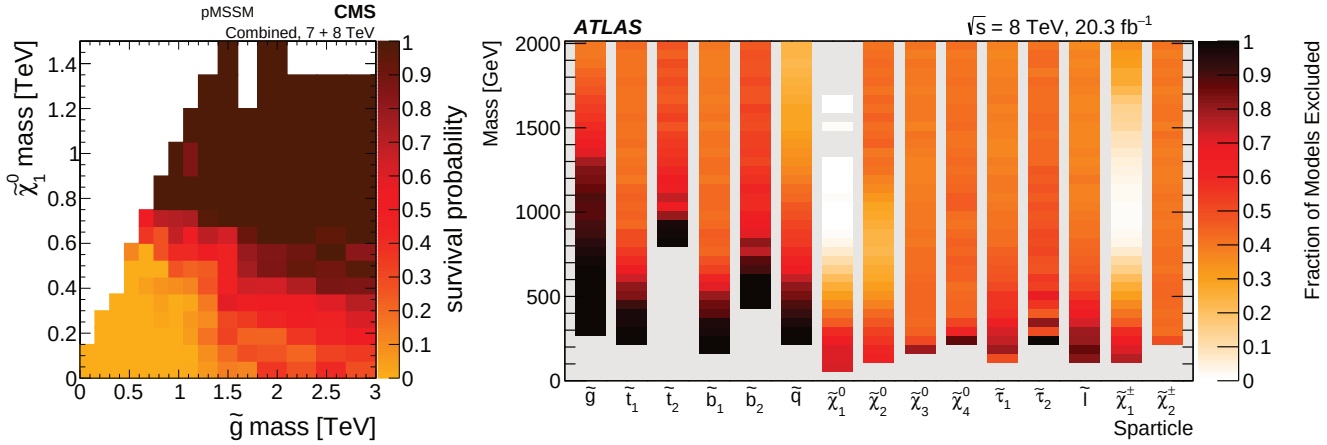

Figure 89.12: The plot on the left shows the survival probability of a pMSSM parameter space model in the gluino-neutralino mass plane after the application of the relevant CMS search results. The plot on the right shows a graphical representation of the ATLAS exclusion power in a pMSSM model. Each vertical bar is a one-dimensional projection of the fraction of models points excluded for each sparticle by ATLAS analyses. The experimental results are obtained from data taken at $\sqrt{s} = 7$ and 8 TeV.

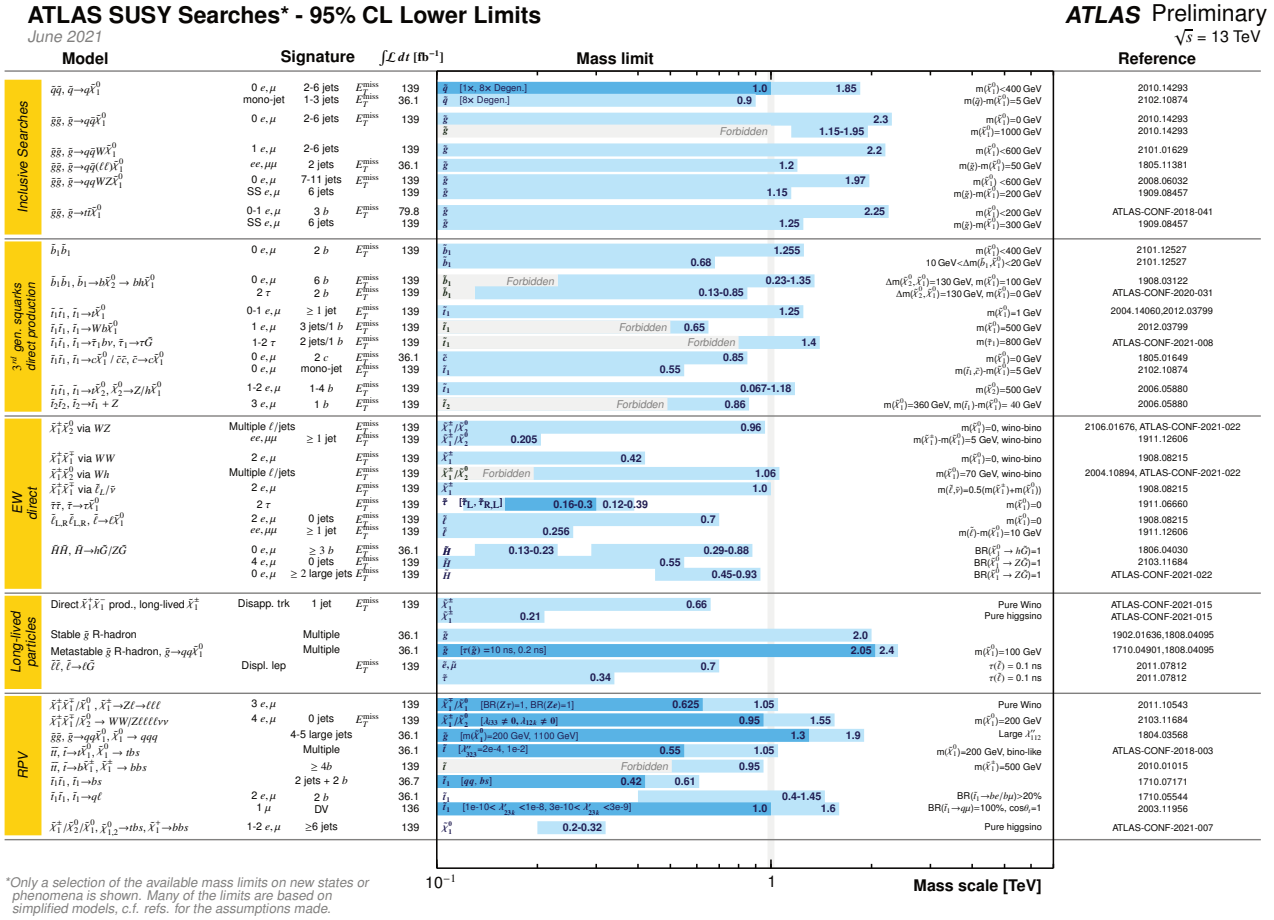

Figure 89.13: Overview of the current landscape of SUSY searches at the LHC. The plot shows exclusion mass limits of ATLAS for different searches and interpretation assumptions. The corresponding results of the CMS experiment are similar.

els for gluino production. However, as shown in the right plot of Fig. 89.12, when a similar analysis for other sparticles is performed it becomes apparent that exclusions on the pMSSM parameter can be significantly less stringent than simplified model limits might suggest. This is especially apparent for the electroweak sector, where even at rather low masses several of the pMSSM test points still survive the constraint of ATLAS searches at $\sqrt{s} = 7$ and 8 TeV. This again indicates that care must be taken when interpreting results from the LHC searches and there are still several scenarios where sparticles below the 1 TeV scale are not excluded, even when considering the most recent results at $\sqrt{s} = 13$ TeV.

Furthermore, the discovery of a Higgs boson with a mass around 125 GeV has triggered many studies regarding the compatibility of SUSY parameter space with this new particle. Much of it is still work in progress and it will be interesting to see how the interplay between the results from direct SUSY searches and more precise

measurements of the properties of the Higgs boson will unfold in the future.

89.12 Summary and Outlook

The absence of any observation of new phenomena at the first run of the LHC at $\sqrt{s} = 7/8$ TeV, and after the second run at $\sqrt{s} = 13$ TeV, places significant constraints on SUSY parameter space. An overview of the current landscape of SUSY searches and limits at the LHC is shown in Figure 89.13, where the ATLAS summary is reported for illustration purposes. Inclusive searches probe production of gluinos at about 2.3 TeV, first and second generation squarks in the range of about 1 to 1.9 TeV, third generation squarks at scales around 600 GeV to 1.2 TeV, electroweak gauginos at scales around $400 - 1100$ GeV, and sleptons around 700 GeV. However, depending on the assumptions made on the underlying SUSY spectrum these limits can also weaken considerably.

With the LHC having reached almost its maximum energy of about $\sqrt{s} = 14$ TeV, future sensitivity improvement will have to originate from more data, the improvement of experimental analysis techniques and the focus on special signatures like the ones arising in long-lived sparticle decays. Therefore, it is expected that the current landscape of SUSY searches and corresponding exclusion limits at the LHC, as, for example, shown in Fig. 89.13 from the ATLAS experiment [270] (CMS results are similar [271]), will not change as rapidly anymore as it did in the past, when the LHC underwent several successive increases of collision energy.

The interpretation of results at the LHC has moved away from constrained models like the CMSSM towards a large set of simplified models, or the pMSSM. On the one hand this move is because the LHC limits have put constrained models like the CMSSM under severe pressure, while on the other hand simplified models leave more freedom to vary parameters and form a better representation of the underlying sensitivity of analyses. However, these interpretations in simplified models do not come without a price: the decomposition of a potentially complicated reality in a limited set of individual decay chains can be significantly incomplete. Therefore, quoted limits in simplified models are only valid under the explicit assumptions made in these models. The recent addition of more comprehensive interpretations in the pMSSM will complement those derived from simplified models and, thus, will enable an even more refined understanding of the probed SUSY parameter space.

In this context, the limit range of $1.5 - 2.3$ TeV on generic colored SUSY particles only holds for light neutralinos, in the R-parity conserving MSSM. Limits on third generation squarks and electroweak gauginos also only hold for light neutralinos, and under specific assumptions for decay modes and slepton masses.

The next LHC runs, with $\sqrt{s}$ between 13 and 14 TeV and significantly larger integrated luminosities (notably the High-Luminosity LHC), will provide a large data sample for future SUSY searches. As mentioned above, the improvement in sensitivity will largely have to come from a larger data set, and evolution of trigger and analysis techniques, since there will be no significant energy increase at the LHC anymore. Although the sensitivity for colored sparticles will increase somewhat as well, the expanded data set will be particularly beneficial for electroweak gaugino searches, and for the more difficult final states presented by compressed particle spectra, stealth SUSY, long-lived sparticles, or R-parity violating scenarios.

90. Axions and Other Similar Particles

Revised October 2021 by A. Ringwald (DESY, Hamburg), L. J Rosenberg (U. Washington) and G. Rybka (U. Washington).

90.1 Introduction

In this section, we list coupling-strength and mass limits for light neutral scalar or pseudoscalar bosons that couple weakly to normal matter and radiation. Such bosons may arise from the spontaneous breaking of a global U(1) symmetry, resulting in a massless Nambu-Goldstone (NG) boson. If there is a small explicit symmetry breaking, either already in the Lagrangian or due to quantum effects such as anomalies, the boson acquires a mass and is called a pseudo-NG boson. Typical examples are axions (a) [1–4] and majorons [5,6], associated, respectively, with a spontaneously broken Peccei-Quinn and lepton-number symmetry.

A common feature of these light bosons ϕ is that their coupling to Standard-Model particles is suppressed by the energy scale that characterizes the symmetry breaking, *i.e.*, the decay constant f. The interaction Lagrangian is

$$\mathcal{L} = f^{-1} J^\mu \partial_\mu \phi \,, \tag{90.1}$$

where J^μ is the Noether current of the spontaneously broken global symmetry. If f is very large, these new particles interact very weakly. Detecting them would provide a window to physics far beyond what can be probed at accelerators.

Axions are of particular interest because the Peccei-Quinn (PQ) mechanism remains perhaps the most credible scheme to preserve CP-symmetry in QCD. Moreover, the cold dark matter (CDM) of the Universe may well consist of axions and they are searched for in dedicated experiments with a realistic chance of discovery.

Originally it was assumed that the PQ scale f_a was related to the electroweak symmetry-breaking scale $v_{\rm EW} = (\sqrt{2} G_{\rm F})^{-1/2} = 247$ GeV. However, the associated "standard" and "variant" axions were quickly excluded—we refer to the Listings for detailed limits. Here we focus on "invisible axions" with $f_a \gg v_{\rm EW}$ as the main possibility.

Axions have a characteristic two-photon vertex, inherited from their mixing with π^0 and η. This coupling allows for the main search strategy based on axion-photon conversion in external magnetic fields [7], an effect that also can be of astrophysical interest. While for axions the product "$a\gamma\gamma$ interaction strength $\times$ mass" is essentially fixed by the corresponding π^0 properties, one may consider a more general class of axion-like particles (ALPs) where the two parameters (coupling and mass) are independent. A number of experiments explore this more general parameter space. ALPs populating the latter are predicted to arise generically, in addition to the axion, in low-energy effective field theories emerging from string theory [8–15]. The latter often contain also very light Abelian vector bosons under which the Standard-Model particles are not charged: so-called hidden-sector photons, dark photons or paraphotons. They share a number of phenomenological features with the axion and ALPs, notably the possibility of hidden photon to photon conversion and of hidden photon dark matter [16–18]. Their physics cases and the current constraints are compiled in Refs. [19–22].

90.2 Theory

90.2.1 *Peccei-Quinn mechanism and axions*

The QCD Lagrangian includes a CP-violating term $\mathcal{L}_\Theta = -\bar{\Theta}\,(\alpha_s/8\pi)\, G^{\mu\nu a} \tilde{G}^a_{\mu\nu}$, where $-\pi \le \bar{\Theta} \le +\pi$ is the effective Θ parameter after diagonalizing quark masses, $G^a_{\mu\nu}$ is the color field strength tensor, and $\tilde{G}^{a,\mu\nu} \equiv \epsilon^{\mu\nu\lambda\rho} G^a_{\lambda\rho}/2$, with $\varepsilon^{0123} = 1$, its dual. This term induces an electric dipole moment (EDM) of the neutron of size $d_n = C_{\rm EDM}\, e\, \bar{\Theta}$, where $C_{\rm EDM} = 2.4(1.0) \times 10^{-16}$ cm [23]. Experimental upper bounds on the latter, $|d_n| < 1.8 \times 10^{-26}\, e$ cm [24,25], imply $|\bar{\Theta}| \lesssim 10^{-10}$ even though $\bar{\Theta} = \mathcal{O}(1)$ is otherwise completely satisfactory. The spontaneously broken global Peccei-Quinn symmetry $\mathrm{U}(1)_{\rm PQ}$ was introduced to solve this "strong CP problem" [1,2], the axion being the pseudo-NG boson of $\mathrm{U}(1)_{\rm PQ}$ [3,4]. This symmetry is broken due to the axion's anomalous triangle coupling to gluons,

$$\mathcal{L} = \left(\frac{a}{f_a} - \bar{\Theta} \right) \frac{\alpha_s}{8\pi}\, G^{\mu\nu a} \tilde{G}^a_{\mu\nu} \,, \tag{90.2}$$

where a is the axion field and f_a the axion decay constant. Color anomaly factors have been absorbed in the normalization of f_a which is defined by this Lagrangian. Thus normalized, f_a is the quantity that enters all low-energy phenomena [26]. Non-perturbative topological fluctuations of the gluon fields in QCD induce a potential for a whose minimum is at $a = \bar{\Theta} f_a$, thereby canceling the $\bar{\Theta}$ term in the QCD Lagrangian and thus restoring CP symmetry.

The resulting axion mass, in units of the PQ scale f_a, is identical to the square root of the topological susceptibility in QCD, $m_a f_a = \sqrt{\chi}$. The latter can be evaluated further [27,28], exploiting the chiral limit (masses of up and down quarks much smaller than the scale of QCD), yielding $m_a f_a = \sqrt{\chi} \approx f_\pi m_\pi$, where $m_\pi = 135$ MeV and $f_\pi \approx 92$ MeV. In more detail one finds, by including $\mathcal{O}(\alpha)$ QED corrections and next-to-next-to-leading order (NNLO) corrections in chiral perturbation theory [29],

$$m_a = 5.691(51) \left(\frac{10^9 \text{ GeV}}{f_a} \right) \text{meV} \,. \tag{90.3}$$

A direct calculation of the topological susceptibility via QCD lattice simulations finds almost the same central value, albeit with an about five times larger error bar [30].

The axion's anomalous coupling to gluons induces, at energies below the confinement scale of QCD, a model-independent coupling of the axion to the operator giving rise to the EDM of the nucleon (N),

$$\mathcal{L}_{aN\gamma} = -\frac{i}{2} g_{aN\gamma}\, a\, \overline{\Psi}_N \sigma_{\mu\nu} \gamma_5 \Psi_N F^{\mu\nu} \,, \tag{90.4}$$

where the couplings constants of the neutron (n) and the proton (p) are given by

$$g_{an\gamma} = -g_{ap\gamma} = e\, \frac{C_{\rm EDM}}{f_a} = (3.7 \pm 1.5) \times 10^{-3} \left(\frac{1}{f_a} \right) \frac{1}{\text{GeV}} \,. \tag{90.5}$$

This coupling, as a function of the axion mass, is displayed in Fig. 90.1, where the thickness of the yellow band presents the theoretical uncertainty given in Eq. (90.5).

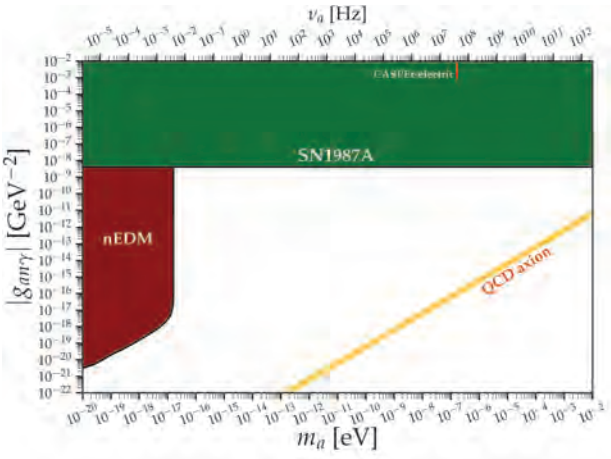

Figure 90.1: Exclusion plot for ALP-EDM coupling as described in the text. Figure courtesy of Ciaran O'Hare [31].

Axions with $f_a \gg v_{\rm EW}$ evade almost all current experimental limits. One generic class of models invokes "hadronic axions" where new heavy quarks carry $\mathrm{U}(1)_{\rm PQ}$ charges, leaving ordinary quarks and leptons without tree-level axion couplings. The archetype is the KSVZ model [32,33], where in addition the heavy new quarks are electrically neutral. Another generic class requires at least two Higgs doublets and ordinary quarks and leptons carry PQ charges, the archetype being the DFSZ model [34,35]. All of these models contain at least one electroweak singlet scalar that acquires a vacuum expectation value and thereby breaks the PQ

symmetry. The KSVZ and DFSZ models are frequently used as benchmark examples, but other models exist where both heavy quarks and Higgs doublets carry PQ charges. In supersymmetric models, the axion is part of a supermultiplet and thus inevitably accompanied by a spin-0 saxion and a spin-1/2 axino, which both also have couplings suppressed by f_a and are expected to have large masses due to supersymmetry breaking [36].

90.2.2 *Model-dependent axion couplings*

Although the generic axion interactions scale approximately with f_π/f_a from the corresponding π^0 couplings, there are non-negligible model-dependent factors and uncertainties. The axion's two-photon interaction plays a key role for many searches,

$$\mathcal{L}_{a\gamma\gamma} = -\frac{g_{a\gamma\gamma}}{4}\, a\, F_{\mu\nu}\tilde{F}^{\mu\nu} = g_{a\gamma\gamma}\, a\, \mathbf{E}\cdot\mathbf{B}\,, \tag{90.6}$$

where F is the electromagnetic field-strength tensor and $\tilde{F}^{\mu\nu} \equiv \epsilon^{\mu\nu\lambda\rho}F_{\lambda\rho}/2$, with $\varepsilon^{0123} = 1$, its dual. The coupling constant is [37]

$$g_{a\gamma\gamma} = \frac{\alpha}{2\pi f_a}\left(\frac{E}{N} - 1.92(4)\right) = \left(0.203(3)\frac{E}{N} - 0.39(1)\right)\frac{m_a}{\mathrm{GeV}^2}\,, \tag{90.7}$$

where E and N are the electromagnetic and color anomalies of the axial current associated with the axion. In grand unified models, and notably for DFSZ [34, 35], $E/N = 8/3$, whereas for KSVZ [32, 33] $E/N = 0$ if the electric charge of the new heavy quark is taken to vanish. In general, a broad range of E/N values is possible [38–41], as indicated by the diagonal yellow band in Fig. 90.2, whose width is roughly determined by the boundary values $E/N = 44/3$ and $E/N = 5/3$, respectively. However, this band still does not exhaust all the possibilities. In fact, there exist classes of QCD axion models whose photon couplings populate the entire still-allowed region outside the yellow band in Fig. 90.2 [42–46], motivating axion search efforts over a wide range of masses and couplings.

The two-photon decay width is

$$\Gamma_{a\to\gamma\gamma} = \frac{g_{a\gamma\gamma}^2 m_a^3}{64\,\pi} = 1.1\times10^{-24}\ \mathrm{s}^{-1}\left(\frac{m_a}{\mathrm{eV}}\right)^5. \tag{90.8}$$

The second expression uses Eq. (90.7) with $E/N = 0$. Axions decay faster than the age of the Universe if $m_a \gtrsim 20$ eV.

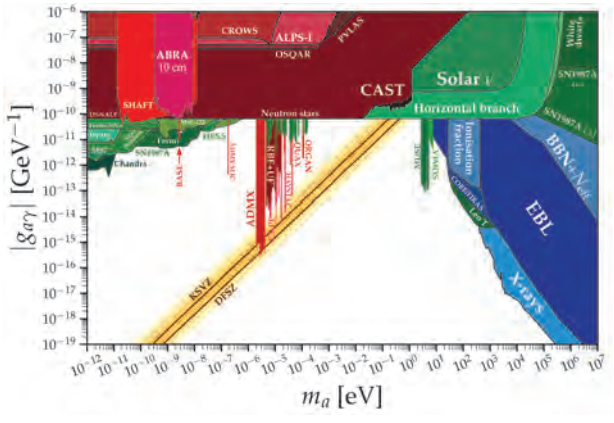

Figure 90.2: Exclusion plot for ALP-photon coupling as described in the text. Figure courtesy of Ciaran O'Hare [31].

The interaction with fermions f has derivative form and is invariant under a shift $a \to a + a_0$ as behooves a NG boson,

$$\mathcal{L}_{aff} = \frac{C_f}{2f_a}\,\partial_\mu a\,\bar{\Psi}_f\gamma^\mu\gamma_5\Psi_f\,. \tag{90.9}$$

Here, Ψ_f is the fermion field, m_f its mass, and C_f a model-dependent coefficient. The dimensionless combination $g_{aff} \equiv C_f m_f/f_a$ plays the role of a Yukawa coupling and $\alpha_{aff} \equiv g_{aff}^2/4\pi$ of a "fine-structure constant." The often-used pseudoscalar form $\mathcal{L}_{aff} = -\mathrm{i}\,(C_f m_f/f_a)\,a\,\bar{\Psi}_f\gamma_5\Psi_f$ need not be equivalent to the appropriate derivative structure, for example when two NG bosons are attached to one fermion line as in axion emission by nucleon bremsstrahlung [47–49].

In hadronic axion models, C_e vanishes at tree level, but is then generated radiatively at one loop [50, 51],

$$C_e \simeq \frac{3\alpha^2}{4\pi^2}\left[\frac{E}{N}\log\left(\frac{f_a}{m_e}\right) - 1.92\log\left(\frac{\Lambda_\chi}{m_e}\right)\right], \tag{90.10}$$

where $\Lambda_\chi \simeq 1$ GeV is the chiral symmetry breaking scale. In the DFSZ model [34,35], the tree-level coupling coefficient to electrons is [50]

$$C_e = \frac{\sin^2\beta}{3}\,, \tag{90.11}$$

where $\tan\beta$ is the ratio of the vacuum expectation values of the two Higgs doublets giving masses to the up- and down-type quarks, respectively: $\tan\beta = v_u/v_d$. The resulting prediction for the axion-electron coupling, as a function of the axion mass, for the KSVZ axion ($E/N = 0$), hadronic axions, with $5/3 \le E/N \le 44/3$, and the DFSZ axion is displayed in Fig. 90.3. For the DFSZ range we have taken into account the constraint $0.28 \lesssim \tan\beta \lesssim 140$ [52] arising from the requirement of perturbative unitarity of the Yukawa couplings of Standard Model fermions.

For nucleons, $C_{p,n}$ have been determined as [37]

$$\begin{aligned} C_p &= -0.47(3) + 0.88(3)C_u - 0.39(2)C_d - 0.038(5)C_s \\ &\quad - 0.012(5)C_c - 0.009(2)C_b - 0.0035(4)C_t\,, \\ C_n &= -0.02(3) + 0.88(3)C_d - 0.39(2)C_u - 0.038(5)C_s \\ &\quad - 0.012(5)C_c - 0.009(2)C_b - 0.0035(4)C_t\,, \end{aligned} \tag{90.12}$$

in terms of the corresponding model-dependent quark couplings C_q, $q = u, d, s, c, b, t$. For hadronic axions, the latter vanish at tree-level, which means that C_n is expected to be much smaller than C_p. In the DFSZ model, $C_u = C_c = C_t = \frac{1}{3}\cos^2\beta$ and $C_d = C_s = C_b = \frac{1}{3}\sin^2\beta$, and C_p and C_n, as functions of β,

$$\begin{aligned} C_p &= -0.435\sin^2\beta + (-0.182 \pm 0.025)\,, \\ C_n &= 0.414\sin^2\beta + (-0.160 \pm 0.025)\,, \end{aligned} \tag{90.13}$$

The resulting prediction for the axion-neutron coupling, as a function of the axion mass, for the KSVZ axion and the DFSZ axion is displayed in Fig. 90.4.

The axion-pion interaction is given by the Lagrangian [51]

$$\mathcal{L}_{a\pi} = \frac{C_{a\pi}}{f_\pi f_a}\,\partial_\mu a\left(\pi^0\pi^+\partial_\mu\pi^- + \pi^0\pi^-\partial_\mu\pi^+ - 2\pi^+\pi^-\partial_\mu\pi^0\right), \tag{90.14}$$

where $C_{a\pi} = (1-z)/[3(1+z)]$ in hadronic models and $C_{a\pi} = (1-z)/[3(1+z)] - (1/9)\cos 2\beta$ in the DFSZ model [41], with $z = m_u/m_d = 0.48(3)$ [37].

90.3 Laboratory Searches

90.3.1 *Light shining through walls*

Searching for "invisible axions" is extremely challenging due to its extraordinarily feeble coupling to normal matter and radiation. Currently, the most promising approaches rely on the axion-two-photon interaction, allowing for axion-photon conversion in external electric or magnetic fields [7]. For the Coulomb field of a charged particle, the conversion is best viewed as a scattering process, $\gamma + Ze \leftrightarrow Ze + a$, called Primakoff effect [53]. In the other extreme of a macroscopic field, usually a large-scale B-field, the momentum transfer is small, the interaction is coherent over a large distance, and the conversion is best viewed as an axion-photon oscillation phenomenon in analogy to neutrino flavor oscillations [54].

Photons propagating through a transverse magnetic field, with incident $\mathbf{E}_\gamma$ and magnetic field $\mathbf{B}$ parallel, may convert into axions. For $m_a^2 L/2\omega \ll 2\pi$, where L is the length of the B field

region and ω the photon energy, the resultant axion beam is coherent with the incident photon beam and the conversion probability is $\Pi \sim (1/4)(g_{a\gamma\gamma}BL)^2$. A practical realization uses a laser beam propagating down the bore of a superconducting dipole magnet (like the bending magnets in high-energy accelerators). If another magnet is in line with the first, but shielded by an optical barrier, then photons may be regenerated from the pure axion beam [55,56]. The overall probability is $P(\gamma \to A \to \gamma) = \Pi^2$.

The first such Light-Shining-through-Walls (LSW) experiment was performed by the BFRT (Brookhaven-Fermilab-Rochester-Trieste) collaboration. It utilized two magnets of length $L = 4.4$ m and $B = 3.7$ T and found $|g_{a\gamma\gamma}| < 6.7 \times 10^{-7}$ GeV^{-1} at 95% CL for $m_a < 1$ meV [57,58]. More recently, several such experiments were performed (see Listings) [59–65]. The current best limit, $|g_{a\gamma\gamma}| < 3.5 \times 10^{-8}$ GeV^{-1} at 95% CL for $m_a \lesssim 0.3$ meV (see Fig. 90.2), has been achieved by the OSQAR (Optical Search for QED Vacuum Birefringence, Axions, and Photon Regeneration) experiment, which exploited two 9 T LHC dipole magnets and an 18.5 W continuous wave laser emitting at the wavelength of 532 nm [65]. The ALPS I (Any Light Particle Search I) experiment achieved a similar sensitivity [63], see Fig. 90.2. Some of these experiments have also reported limits for scalar bosons where the photon $\mathbf{E}_\gamma$ must be chosen perpendicular to the magnetic field $\mathbf{B}$.

The concept of resonantly enhanced photon regeneration may open unexplored regions of coupling strength [66–68]. In this scheme, both the production and detection magnets are within Fabry-Perot optical cavities and actively locked in frequency. The $\gamma \to a \to \gamma$ rate is enhanced by a factor $\mathcal{F}\mathcal{F}'/\pi^2$ relative to a single-pass experiment, where $\mathcal{F}$ and $\mathcal{F}'$ are the finesses of the two cavities. The resonant enhancement could be of order $10^{(10-12)}$, improving the $g_{a\gamma\gamma}$ sensitivity by $10^{(2.5-3)}$. The experiment ALPS II (Any Light Particle Search II) is based on this concept and aims at an improvement of the current laboratory bound on $g_{a\gamma\gamma}$ by a factor $\sim 10^3$ in the year 2022 [69].

Resonantly enhanced photon regeneration has already been exploited in experiments searching for "radiowaves shining through a shielding" [70–73]. For $m_a \lesssim 10^{-5}$ eV, the upper bound on $g_{a\gamma\gamma}$ established by the CROWS (CERN Resonant Weakly Interacting sub-eV Particle Search) experiment [74] is slightly less stringent than the one set by OSQAR, see Fig. 90.2.

90.3.2 *Photon polarization*

An alternative to regenerating the lost photons is to use the beam itself to detect conversion: the polarization of light propagating through a transverse B field suffers dichroism and birefringence [75]. Dichroism: The $E_\parallel$ component, but not $E_\perp$, is depleted by axion production, causing a small rotation of linearly polarized light. For $m_a^2 L/2\omega \ll 2\pi$, the effect is independent of m_a. For heavier axions, it oscillates and diminishes as m_a increases, and it vanishes for $m_a > \omega$. Birefringence: This effect occurs because there is mixing of virtual axions in the $E_\parallel$ state, but not for $E_\perp$. Hence, linearly polarized light will develop elliptical polarization. Higher-order QED also induces vacuum magnetic birefringence (VMB). A search for these effects was performed in the same dipole magnets of the BFRT experiment mentioned before [76]. The dichroic rotation gave a stronger limit than the ellipticity rotation: $|g_{a\gamma\gamma}| < 3.6 \times 10^{-7}$ GeV^{-1} at 95% CL, for $m_a < 5 \times 10^{-4}$ eV. The ellipticity limits are better at higher masses, as they fall off smoothly and do not terminate at m_a.

In 2006, the PVLAS collaboration reported a signature of magnetically induced vacuum dichroism that could be interpreted as the effect of a pseudoscalar with $m_a = 1$–1.5 meV and $|g_{a\gamma\gamma}| = (1.6$–$5) \times 10^{-6}$ GeV^{-1} [77]. Later, it turned out that these findings are due to instrumental artifacts [78]. This particle interpretation is also excluded by the above photon regeneration searches that were inspired by the original PVLAS result. The fourth generation setup of the PVLAS experiment has published results on searches for VMB (see Fig. 90.2) and dichroism [79]. The bounds from the non-observation of the latter on $g_{a\gamma\gamma}$ are slightly weaker than the ones from OSQAR.

90.3.3 *Long-range forces*

New bosons would mediate long-range forces, which are severely constrained by "fifth force" experiments [80]. Those looking for new mass-spin couplings provide significant constraints on pseudoscalar bosons [81–86], see for example in Fig. 90.4 the limit on the axion-neutron coupling [87] from torsion balance tests of the gravitational inverse square law [88]. Presently, the most restrictive limits are obtained from combining long-range force measurements with stellar cooling arguments [89, 90]. For the moment, any of these limits are far from realistic values expected for the QCD axion. Still, these efforts provide constraints on more general low-mass bosons.

In Ref. [91], a method was proposed that can extend the search for axion-mediated spin-dependent forces by several orders of magnitude. By combining techniques used in nuclear magnetic resonance and short-distance tests of gravity, this method appears to be sensitive to the QCD axion in the μeV – meV mass range, independent of the cosmic axion abundance, if axions have a CP-violating interaction with nuclei as large as the current experimental bound on the electric dipole moment of the neutron allows. The ARIADNE (Axion Resonant InterAction DetectioN Experiment) is under development and employs this approach to search for axion-mediated spin-dependent short-range interactions between a hyper-polarized 3-He sample and an unpolarized tungsten source mas [92]. The method relies on superconducting magnetic shielding to screen the sample from ordinary magnetic field noise. Experimental tests to demonstrate the requirements of ARIADNE, including characterization of the magnetic field backgrounds, are under way [93, 94].

90.4 Axions from Astrophysical Sources

90.4.1 *Stellar energy-loss limits*

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, *etc.*) are produced in hot astrophysical plasma, and can thus transport energy out of stars. The coupling strength of these particles with normal matter and radiation is bounded by the constraint that stellar lifetimes or energy-loss rates are not in conflict with observation [95, 96].

We begin this discussion with our Sun and concentrate first on hadronic axions. They are produced predominantly by the Primakoff process $\gamma + Ze \to Ze + a$. Integrating over a standard solar model yields the axion luminosity [97]

$$L_a = g_{10}^2 \times 1.85 \times 10^{-3}\, L_\odot\,, \tag{90.15}$$

where $g_{10} = |g_{a\gamma\gamma}| \times 10^{10}$ GeV. The maximum of the spectrum is at 3.0 keV, the average at 4.2 keV, and the number flux at Earth is $g_{10}^2 \times 3.75 \times 10^{11}$ cm^{-2} s^{-1}. The solar photon luminosity is fixed, so energy losses due to the Primakoff process require enhanced nuclear energy production and thus enhanced neutrino fluxes. The all-flavor measurements by SNO (Sudbury Neutrino Observatory), together with a standard solar model, imply $L_a \lesssim 0.10\, L_\odot$, corresponding to $g_{10} \lesssim 7$ [98], mildly superseding a similar limit from helioseismology (sound speed, surface helium and convective radius) [99]. In Ref. [100], this limit was improved to $g_{10} < 4.1$ (at $3\,\sigma$), see Fig. 90.2, exploiting a new statistical analysis that combined helioseismology and solar neutrino observations, including theoretical and observational errors, and accounting for tensions between input parameters of solar models, in particular the solar element abundances. Going beyond the hadronic axion, Ref. [98] considered also a non-zero axion-electron coupling and obtained the bound on the latter displayed in Fig. 90.3.

A more restrictive limit derives from globular-cluster (GC) stars that allow for detailed tests of stellar-evolution theory. The stars on the horizontal branch (HB) in the color-magnitude diagram have reached helium burning with a core-averaged energy release of about 80 erg g^{-1} s^{-1}, compared to Primakoff axion losses of $g_{10}^2\, 30$ erg g^{-1} s^{-1}. The accelerated consumption of helium reduces the HB lifetime by about $80/(80{+}30\, g_{10}^2)$. Number counts of HB stars in a large sample of 39 Galactic GCs compared with the number of red giants (that are not much affected by Primakoff losses) give a weak indication of non-standard losses which may be accounted by Primakoff-like axion emission, if the photon coupling is in the range $|g_{a\gamma\gamma}| = (2.9 \pm 1.8) \times 10^{-11}$ GeV^{-1} [101,102]. Still, the upper bound found in this analysis,

$$|g_{a\gamma\gamma}| < 6.6 \times 10^{-11}\,\text{GeV}^{-1}\ (95\%\,\text{CL}), \tag{90.16}$$

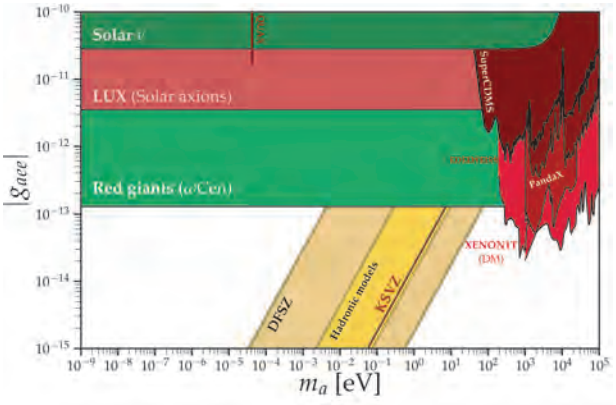

Figure 90.3: Exclusion plot for ALP-electron coupling as described in the text. Figure courtesy of Ciaran O'Hare [31].

represents the strongest limit on $g_{a\gamma\gamma}$ for a wide mass range, see Fig. 90.2. The conservative constraint, Eq. (90.16), on $g_{a\gamma\gamma}$ may be translated to $f_a > 3.4{\times}10^7$ GeV ($m_a < 0.2$ eV), using $E/N = 0$ as in the KSVZ model, or to $f_a > 1.3 \times 10^7$ GeV ($m_a < 0.5$ eV), for the DFSZ axion model, with $E/N = 8/3$, see Fig. 90.2.

If axions couple directly to electrons, the dominant emission processes are atomic axio-recombination and axio-deexcitation, axio-bremsstrahlung in electron-ion or electron-electron collisions, and Compton scattering [103]. Stars in the red giant (RG) branch of the color-magnitude diagram of GCs are particularly sensitive to these processes: they would lead to an extension of the latter to larger brightness. In fact, the RG branch tip – the brightest point of the RG brangh – provides the currently most sensitive method to test the axion coupling to electrons. The strongest bounds on it are derived from analyses of the RG branch tip in several globular clusters [104] and in the Galactic globular cluster ω Centauri [105]. The two analyses lead to very similar results,

$$|g_{aee}| < 1.48{\times}10^{-13} \text{ (95\% CL) and } |g_{aee}| < 1.3{\times}10^{-13} \text{ (95\% CL)}, \quad (90.17)$$

respectively, see Fig. 90.3. Reference [104] finds also a small hint for extra cooling, corresponding to $|g_{aee}| = 0.60^{+0..32}_{-0.58} \times 10^{-13}$, while Ref. [105] does not find any evidence for exotic cooling.

Bremsstrahlung is also efficient in white dwarfs (WDs), where the Primakoff and Compton processes are suppressed by the large plasma frequency. A comparison of the predicted and observed luminosity function of WDs can be used to put limits on $|g_{aee}|$ [106, 107]. An analysis based on detailed WD cooling treatment and data on the WD luminosity function (WDLF) of the Galactic disk found that electron couplings above $|g_{aee}| \gtrsim 3 \times 10^{-13}$ are disfavoured [108]. Lower couplings cannot be discarded from the current knowledge of the WDLF of the Galactic disk. On the contrary, features in some WDLFs can be interpreted as suggestions for electron couplings in the range $7.2 \times 10^{-14} \lesssim |g_{aee}| \lesssim 2.2 \times 10^{-13}$ [108–110]. This hypothesis will be further scrutinized by the Large Synoptic Survey Telescope (LSST) which is expected to increase the sample of WDs in the Galactic halo to hundreds of thousands [111]. This will allow for the determination of independent WDLFs from different Galactic populations, greatly reducing the uncertainties related to star formation histories. For pulsationally unstable WDs (ZZ Ceti stars), the period decrease $\dot{P}/P$ is a measure of the cooling speed. The corresponding observations of a handful pulsating WDs imply additional cooling that can be interpreted also in terms of similar axion losses [112–116]. In fact, the combined analysis of these observations gives a good fit for $|g_{aee}| = 2.9 \times 10^{-13}$ and favours the axion (or ALP) interpretation at slightly more than 2σ [41].

Intriguingly, a $3\,\sigma$ preference for the existence of the axion (or an ALP) is found if one combines the hints of excessive cooling of HB stars, RGs and WDs and allows for both a photon and electron coupling [117]. The best fit is obtained for $|g_{a\gamma\gamma}| \sim 1.4 \times 10^{-11}\,\text{GeV}^{-1}$ and $|g_{aee}| \sim 1.5 \times 10^{-13}$, respectively, where the photon coupling is compatible with zero at 1σ, whereas the electron coupling is non-zero at the level of 3σ [41, 117].

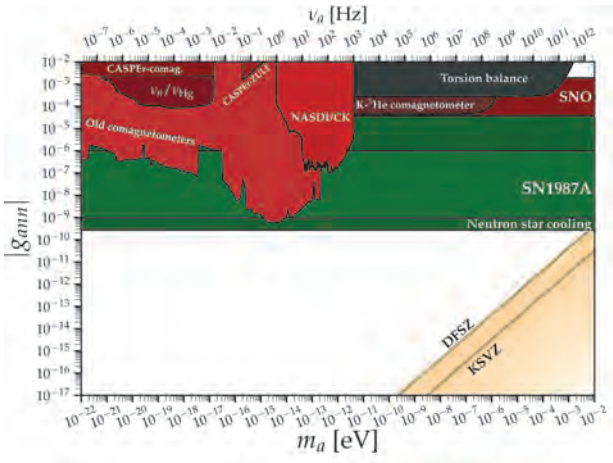

Figure 90.4: Exclusion plot for ALP-neutron coupling as described in the text. Figure courtesy of Ciaran O'Hare [31].

Analogous constraints derive from the measured duration of the neutrino signal of the supernova SN 1987A. Numerical simulations for a variety of cases, including axions and Kaluza-Klein gravitons, reveal that the energy-loss rate of a nuclear medium at the density 3×10^{14} g cm^{-3} and temperature 30 MeV should not exceed about 1×10^{19} erg g^{-1} s^{-1} [118]. The energy-loss rate from nucleon bremsstrahlung, $N + N \rightarrow N + N + a$, is $(C_N/2f_a)^2(T^4/\pi^2 m_N)\,F$. Here F is a numerical factor that represents an integral over the dynamical spin-density structure function because axions couple to the nucleon spin. For realistic conditions, even after considerable effort, one is limited to a heuristic estimate leading to $F \approx 1$ [96]. The SN 1987A limits are of particular interest for hadronic axions where the bounds on $|g_{aee}|$ are moot. Using a proton fraction of 0.3, $g_{ann} = 0$, $F = 1$, and $T = 30$ MeV, one finds $f_a > 4 \times 10^8$ GeV and $m_a < 16$ meV [96]. A more detailed numerical calculation [119] with state of the art SN models, again assuming $g_{ann} = 0$, found that a coupling larger than $|g_{app}| \gtrsim 6 \times 10^{-10}$, would shorten significantly the timescale of the neutrino emission. This result is, not surprisingly, rather close to the estimate in Ref. [96]. Improving the calculation of axion emission via nucleon-nucleon bremsstrahlung beyond the basic one-pion exchange approximation appears to loosen the bound [120, 121]. The latter analysis finds a reduction of the axion emissivity by an order of magnitude if one takes into account the non-vanishing mass of the exchanged pion, the contribution from two-pion exchange, effective in-medium nucleon masses and multiple nucleon scattering, leading to a looser bound

$$g_{ann}^2 + 0.61\, g_{app}^2 + 0.53\, g_{ann}\, g_{app} < 8.26 \times 10^{-19}\,, \quad (90.18)$$

see Fig. 90.4. This analysis, however, still neglects another very efficient mechanism for axion production in a SN: the pion production process, $\pi^- + p \rightarrow a + n$, also induced by the axion coupling to nucleons. Pion production was recognized long ago as being competitive with nucleon bremsstrahlung [122–124]. However, only recently it was shown that the pion abundance in the early stages of a SN is much larger than previously expected [125]. Although a complete study of the SN evolution which includes pions self-consistently does not exist at the moment, it was shown in Ref. [126] that pion induced processes dominate over bremsstrahlung and so strengthen the bound on the axion-nucleon coupling. In any case, with the present understanding of SNe (current lack of self-consistent 3D SN simulations) and the sparse data from SN 1987A, the constraint on the axion-nucleon couplings from SN 1987A should be considered more as indicative than as a sharp bound [119].

If axions interact sufficiently strongly they are trapped. Only about three orders of magnitude in g_{aNN}, where $N = n, p$, or m_a are excluded, see Fig. 90.4. For even larger couplings, the axion

flux would have been negligible, yet it would have triggered additional events in the detectors, excluding a further range [127]. A possible gap between these two SN 1987A arguments was discussed as the "hadronic axion window" under the assumption that $g_{a\gamma\gamma}$ was anomalously small [128]. This range is now excluded by hot dark matter (HDM) bounds (see below).

Further bounds on the axion-nucleon coupling can be derived from observations of the cooling of neutron stars, in particular the neutron star (NS) in the supernova remnant Cassiopeia A (Cas A). Its surface temperature measured over 10 years reveals an unusually fast cooling rate. This rapid cooling of the Cas A NS may be explained by NS minimal cooling with neutron superfluidity and proton superconductivity [129, 130]. The rapid cooling may also arise from a phase transition of the neutron condensate into a multicomponent state [131]. Recently, Ref. [132] analyzed Cas A NS cooling in the presence of axion emission and obtained

$$g_{app}^2 + 1.6 g_{ann}^2 < 1 \times 10^{-18}, \tag{90.19}$$

which is comparable to the SN 1987A bound. Refs. [133, 134] put a less stringent bound on a KSVZ type axion, without an attempt to fit a transient behavior of Cas A,

$$f_a > (5-10) \times 10^7 \text{ GeV (or } g_{app}^2 < (1-6) \times 10^{-17}), \tag{90.20}$$

from the temperatures of Cas A and other NSs. This limit has been confirmed very recently by Ref. [135] focussing again on the CasA NS and finding $f_a > 3 \times 10^7$ GeV (KSVZ) and $f_a > 4.5 \times 10^8$ GeV (DFSZ). The Cas A NS cooling may also be interpreted as a hint for extra cooling caused by the emission of axions from the breaking and re-formation of neutron triplet Cooper pairs [136], requiring a coupling to the neutron of

$$g_{ann}^2 = (1.4 \pm 0.5) \times 10^{-19}, \tag{90.21}$$

corresponding to an axion mass

$$m_a = (2.3 \pm 0.4)\,\text{meV}/C_n. \tag{90.22}$$

However, the astrophysical versus instrumental origin of the observed cooling of the CasA NS is still being debated [137]. On the other hand, Ref. [138] considered another hot young NS in the supernova remnant HESS J1731-347. Its high temperature implies that all the neutrino emission processes except neutron-neutron bremsstrahlung must be strongly suppressed, which can be realized with a negligible neutron triplet gap and a large proton singlet gap. In this setup, the bremsstrahlung from neutrons is the dominant channel for axion emission, from which one obtains a limit

$$g_{ann}^2 < 7.7 \times 10^{-20}\,, \tag{90.23}$$

see Fig. 90.4.

The model-independent axion coupling to the nucleon EDMs, Eq. (90.5), can also be constrained by the non-observation of excess cooling from SN 1987A. Reference [139] presents a determination of the cooling rate due to the axion production process $N + \gamma \to N + a$, leading to the bound

$$|g_{aN\gamma}| < 4 \times 10^{-9}\,\text{GeV}^{-2}\,, \tag{90.24}$$

see Fig. 90.1.

Finally, let us note that if the interpretation of the various hints for additional cooling of stars, reported in this section in terms of emission of axions with $m_a \sim$meV, were correct, SNe would lose a large fraction of their energy as axions. This would lead to a diffuse SN axion background in the Universe with an energy density comparable to the extra-galactic background light [140]. However, there is no apparent way of detecting it or the axion burst from the next nearby SN. On the other hand, neutrino detectors such as IceCube, Super-Kamiokande or a future mega-ton water Cherenkov detector will probe exactly the mass region of interest by measuring the neutrino pulse duration of the next Galactic SN [119].

90.4.2 *Searches for solar axions and ALPs*

Instead of using stellar energy losses to derive axion limits, one can also search directly for these fluxes, notably from the Sun. The main focus has been on ALPs with a two-photon vertex. They are produced by the Primakoff process with a flux given by Eq. (90.15) and an average energy of 4.2 keV, and can be detected at Earth with the reverse process in a macroscopic B-field ("axion helioscope") [7]. In order to extend the sensitivity in mass towards larger values, one can endow the photon with an effective mass in a gas, $m_\gamma = \omega_{\rm plas}$, thus matching the axion and photon dispersion relations [141].

An early implementation of these ideas used a conventional dipole magnet, with a conversion volume of variable-pressure gas with a xenon proportional chamber as x-ray detector [142]. The conversion magnet was fixed in orientation and collected data for about 1000 s/day. Axions were excluded for $|g_{a\gamma\gamma}| < 3.6 \times 10^{-9}$ GeV^{-1} for $m_a < 0.03$ eV, and $|g_{a\gamma\gamma}| < 7.7 \times 10^{-9}$ GeV^{-1} for $0.03 < m_a < 0.11$ eV at 95% CL.

Later, the Tokyo axion helioscope used a superconducting magnet on a tracking mount, viewing the Sun continuously. They reported $|g_{a\gamma\gamma}| < 6 \times 10^{-10}$ GeV^{-1} for $m_a < 0.3$ eV [143,144]. This experiment was recommissioned and a similar limit for masses around 1 eV was reported [145].

The most recent helioscope CAST (CERN Axion Solar Telescope) uses a decommissioned LHC dipole magnet on a tracking mount. The hardware includes grazing-incidence x-ray optics with solid-state x-ray detectors, as well as novel x-ray Micromegas position-sensitive gaseous detectors. Exploiting an IAXO (see below) pathfinder system, CAST has established the limit

$$|g_{a\gamma\gamma}| < 6.6 \times 10^{-11}\ \text{GeV}^{-1} \quad (95\%\ \text{CL}), \tag{90.25}$$

for $m_a < 0.02$ eV [146]. To cover larger masses, the magnet bores are filled with a gas at varying pressure. The runs with ^{4}He cover masses up to about 0.4 eV [147], providing the ^{4}He limits shown in Fig. 90.2. To cover yet larger masses, ^{3}He was used to achieve a larger pressure at cryogenic temperatures. Limits up to 1.17 eV allowed CAST to "cross the axion line" for the KSVZ model [148–150], see Fig. 90.2.

Going to yet larger masses in a helioscope search is not well motivated because of the cosmic HDM bound of $m_a \lesssim 1$ eV (see below). Sensitivity to significantly smaller values of $g_{a\gamma\gamma}$ can be achieved with a next-generation axion helioscope with a much larger magnetic-field cross section. Realistic design options for this "International Axion Observatory" (IAXO) have been studied in some detail [151] and its physics potential has been reviewed recently [152]. Such a next-generation axion helioscope may also push the sensitivity in the product of couplings to photons and to electrons, $g_{a\gamma\gamma}g_{aee}$, into a range beyond stellar energy-loss limits and test the hypothesis that WD, RG, and HB cooling is dominated by axion emission [153, 154]. As a first step towards IAXO, an intermediate experimental stage called BabyIAXO is currently under preparation at DESY [155].

Other Primakoff searches for solar axions and ALPs have been carried out using crystal detectors, exploiting the coherent conversion of axions into photons when the axion angle of incidence satisfies a Bragg condition with a crystal plane [156–160]. However, none of these limits is more restrictive than the one derived from the constraint on the solar axion luminosity ($L_a \lesssim 0.10\,L_\odot$) discussed earlier.

Direct detection experiments searching for dark matter (DM) consisting of weakly interacting massive particles have also the capability to search for solar axions and ALPs. For low masses, $m_a \lesssim 100\,$eV, the LUX experiment [161] has provided the most stringent bound among those experiments on the axion-electron coupling constant,

$$|g_{aee}| < 3.5 \times 10^{-12} \quad (90\%\ \text{CL}), \tag{90.26}$$

see Fig. 90.3, by exploiting the axio-electric effect in liquid xenon. A slightly less stringent limit was set by PandaX-II [162]. However, as obvious from the same figure, this technique has not reached the sensitivity of energy-loss considerations in stars. Recently, the XENON1T collaboration has reported an excess in low

energy electronic recoil data peaking around 2-3 keV [163]. A possible solar axion interpretation is, however, in stark contrast with the constraints from stellar astrophysics [164–166].

90.4.3 *Conversion of astrophysical axion fluxes*

Large-scale B fields exist in astrophysics that can induce axion-photon oscillations. In practical cases, B is much smaller than in the laboratory, whereas the conversion region L is much larger. Therefore, while the product BL can be large, realistic sensitivities are usually restricted to very low-mass particles, far away from the "axion band" in a plot like Fig. 90.2.

One example is SN 1987A, which would have emitted a burst of ALPs due to the Primakoff production in its core. They would have partially converted into γ-rays in the Galactic B-field. The lack of a gamma-ray signal in the GRS instrument of the SMM satellite in coincidence with the observation of the neutrinos emitted from SN 1987A therefore provides a strong bound on their coupling to photons [167,168]. This bound has been revisited and the underlying physics has been brought to the current state-of-the-art, as far as modeling of the supernova and the Milky-Way magnetic field are concerned, resulting in the limit [169]

$$|g_{a\gamma\gamma}| < 5.3 \times 10^{-12}\ \text{GeV}^{-1},\ \text{for}\ \ m_a \lesssim 4.4 \times 10^{-10}\ \text{eV}, \quad (90.27)$$

see Fig. 90.2.

Reference [170] reports no evidence of a γ-ray burst in observations of extragalactic SNe with the Fermi Large Area Telescope (LAT). Under the assumption that at least one SN was contained within the LAT field of view, the authors derive an upper bound on the axion photon coupling which is about a factor of 5 weaker than the one from SN 1987A, see Fig. 90.2.

The cumulative emission of ALPs from all past core-collapse SNe would lead to a diffuse gamma-ray flux peaked at energies $\sim 50 - 100\,\text{MeV}$ which can convert in the Galactic magnetic field into photons. Using Fermi-LAT measurements of the diffuse γ-ray flux, Ref. [171] obtains a conservative bound on the photon coupling, $|g_{a\gamma\gamma}| < 5 \times 10^{-10}\ \text{GeV}^{-1}$, for $m_a \lesssim 10^{-11}\,\text{eV}$, see see Fig. 90.2, which can be decreased by nearly three orders of magnitude, if an ALP-nucleon coupling of maximal phenomenologically allowed strength, $|g_{aNN}| \sim 10^{-9}$, is allowed.

We use the first observation of Betelgeuse in hard x rays to perform a novel search for axionlike particles (ALPs). Betelgeuse is not expected to be a standard source of x rays, but light ALPs produced in the stellar core could be converted back into photons in the Galactic magnetic field, producing a detectable flux that peaks in the hard x-ray band ($E_\gamma > 10keV$). Using a 50 ks observation of Betelgeuse by the NuSTAR satellite telescope, we find no significant excess of events above the expected background. Using models of the regular Galactic magnetic field in the direction of Betelgeuse, we set a 95% C.L. upper limit on the ALP-photon coupling of $g_{a\gamma} < (0.5 - 1.8) \times 10^{-11} GeV^{-1}$ (depending on magnetic field model) for ALP masses $m_a < (5.5 - 3.5) \times 10^{-11} eV$.

Hot, young stars, such as Wolf-Rayet stars, are efficiently producing ALPs with energies $\sim 10 - 100\,\text{keV}$ via the Primakoff effect. Large numbers of those stars are hosted by the Galactic Quintuplet and Westerlund 1 super star clusters (SSCs). The non-observation of hard x-rays originating from axion-photon conversion in the Galactic magnetic field in archival NuSTAR (Nuclear Spectroscopic Telescope Array) data from these SSCs allows to set a bound on the axion-photon coupling [172], $|g_{a\gamma\gamma}| < 3.6 \times 10^{-12}\,\text{GeV}^{-1}$, for $m_a \lesssim 5 \times 10^{-11}\,\text{eV}$, see Fig. 90.2. A somewhat weaker bound in the same mass range was established exploiting NuSTAR data on Betelgeuse [173].

A hard x-ray excess in data from the nearby Magnificent Seven isolated NSs [174] may be explained by ALPs produced in the core those stars and converted in the surrounding magnetic field, with $|g_{aNN} g_{a\gamma\gamma}| \in (2 \times 10^{-21}, 10^{-18})\,\text{GeV}^{-1}$, for $m_a \lesssim 10^{-5}\,\text{eV}$ [175]. The non-observation of an x-ray excess from the magnetic white dwarf RE J0317-853 [176] by Chandra yields the constraint $|g_{aee} g_{a\gamma\gamma}| \lesssim 1.3 \times 10^{-25}\,\text{GeV}^{-1}$, for $m_a \ll 10^{-5}\,\text{eV}$ [177], which provides a non-trivial constraint on the ratio g_{aee}/g_{aNN} for axion models explaining the Magnificent Seven x-ray excess.

90.4.4 *Conversion of astrophysical photon fluxes*

Magnetically induced oscillations between photons and ALPs can modify the photon fluxes from distant sources in various ways, featuring (i) frequency-dependent dimming, (ii) modified polarization, and (iii) avoiding absorption by propagation in the form of axions.

For example, dimming of SNe Ia could influence the interpretation in terms of cosmic acceleration [178], although it has become clear that photon-ALP conversion could only be a subdominant effect [179]. Searches for linearly polarized emission from magnetized white dwarfs [180] and changes of the linear polarization from radio galaxies (see, e.g., Ref. [181]) provide limits close to $g_{a\gamma\gamma} \sim 10^{-11}\ \text{GeV}^{-1}$, for masses $m_a \lesssim 10^{-7}$ eV and $m_a \lesssim 10^{-15}$ eV, respectively, albeit with uncertainties related to the underlying assumptions. Even stronger limits, $g_{a\gamma\gamma} \lesssim 2 \times 10^{-13}\ \text{GeV}^{-1}$, for $m_a \lesssim 10^{-14}$ eV, have been obtained by exploiting high-precision measurements of quasar polarizations [182].

Remarkably, it appears that the Universe could be too transparent to TeV γ-rays that should be absorbed by pair production on the extra-galactic background light [183–187]. The situation is not conclusive at present [188–191], but the possible role of photon-ALP oscillations in TeV γ-ray astronomy is tantalizing [192–194]. Fortunately, the region in ALP parameter space, $g_{a\gamma\gamma} \sim 10^{-12} - 10^{-10}\ \text{GeV}^{-1}$ for $m_a \lesssim 10^{-7}$ eV [195], required to explain the anomalous TeV transparency of the Universe, could be conceivably probed by the next generation of laboratory experiments (ALPS II) and helioscopes (IAXO) mentioned above.

This parameter region can also be probed by searching for an irregular behavior of the gamma ray spectrum of distant active galactic nuclei (AGN), expected to arise from photon-ALP mixing in a limited energy range. In this type of studies, the uncertainty in the magnetic field around the source needs to be taken into account. This typically leads to a range of limits on the ALP-photon coupling that depend on the modeling assumptions. The H.E.S.S. collaboration has set a limit of $|g_{a\gamma\gamma}| \lesssim 2.1 \times 10^{-11}\ \text{GeV}^{-1}$, for $1.5 \times 10^{-8}\ \text{eV} \lesssim m_a \lesssim 6.0 \times 10^{-8}$ eV, from the non-observation of an irregular behavior of the spectrum of the AGN PKS 2155-304 [196], see Fig. 90.2. The Fermi-LAT collaboration has put an even more stringent limit on the ALP-photon coupling [197] from observations of the gamma ray spectrum of NGC 1275, the central galaxy of the Perseus cluster, see Fig. 90.2. A similar analysis has been carried out in Ref. [198], using Fermi-LAT data of PKS 2155-304, and in Ref. [199], using ARGO-YBJ and Fermi-LAT data of Mrk 421 [199], see Fig. 90.2. However, these constraints were obtained under certain theoretical assumptions about magnetic fields surrounding the sources, not confirmed yet by direct astronomical observations in these particular directions; this introduces large systematic uncertainties in the reported constraints [200].

Evidence for spectral irregularities has been reported in Galactic sources, such as pulsars and supernova remnants, and has been interpreted as hints for ALPs [201, 202] (see also discussion in Ref. [203] and references therein). However, the inferred ALP parameters, $|g_{a\gamma\gamma}| \sim 10^{-10}\,\text{GeV}^{-1}$, $m_a \sim$ neV, are in tension with the CAST helioscope bounds. Reference [203] updated the analysis of the pulsar signal region including astrophysical nuisance parameters and correctly deriving confidence intervals on ALP parameters by means of Monte Carlo simulations. The tension with the CAST bounds can be evaded if environmental effects in matter, which would suppress the ALP production in dense astrophysical plasmas like the solar interior, are invoked. If this explanation is correct, the claimed ALP signal would be in reach of the next-generation LSW experiment ALPS II. Other ways to make the CAST bound compatible with photon-ALP conversions in the low-density Galactic medium are invoking photon-ALP-dark photon oscillations [204] or the existence of a number of 'hidden' ALPs [205].

At smaller masses, $m_a \lesssim 10^{-12}\,\text{eV}$, galaxy clusters become highly efficient at interconverting ALPs and photons at x-ray energies. Constraints on spectral irregularities in the spectra of luminous x-ray sources (Hydra A, M87, NGC 1275, NGC 3862, Seyfert galaxy 2E3140; taken by Chandra and XMM-Newton) located in or behind galaxy clusters then lead to stringent upper

limits on the ALP-photon coupling [206–211], (for the limits exploiting spectra from Hydra and M87 from Refs. [206] and [208], respectively, see Fig. 90.2). Reference [211] recently performed the most sensitive x-ray searches for ALPs to date by employing Chandra's High-Energy Transmission Gratings that allow for an unsurpassed spectral resolution. New observations of the AGN NGC 1275 then led to the bound

$$|g_{a\gamma\gamma}| < 8 \times 10^{-13}\,\mathrm{GeV}^{-1} \quad (99.7\%\ \mathrm{CL}) \tag{90.28}$$

for light ALPs, see Fig. 90.2.

90.4.5 *Finite density effects*

If the QCD axion sector has a discrete, $\mathbb{Z}_{\mathcal{N}}$, shift symmetry, its potential is much shallower, and its mass, in units of its decay constant, $m_a f_a \simeq (3\pi)^{-1/4}\mathcal{N}^{3/4}\,2^{-\mathcal{N}/2}\,m_\pi f_\pi$, is smaller than the one of the canonical QCD axion by an exponential factor $\propto 2^{-\mathcal{N}/2}$ [44, 45]. This opens up the parameter space over which one should search for a QCD axion towards the left of the yellow canonical QCD axion band in Fig. 90.1, Fig. 90.2, Fig. 90.3, and Fig. 90.4. Novel bounds apply to this exceptionally light QCD axion due to finite density effects [212–214]. In fact, in dense stellar media, the minimum of the axion potential may be shifted to π. This has a number of phenomenological consequences that span from the modification of nuclear processes in stars due to $\theta = \mathcal{O}(\pi)$ to modifications in the orbital decay of binary systems (and subsequently in the emitted gravitational waves).

In fact, $\theta \sim 1$ in the solar core would lead to an increased proton-neutron mass difference, which would prohibit the neutrino line corresponding to the ^{7}Be-^{7}Li mass difference observed by Borexino [215].

Moreover, the fact that the position of the minimum of the axion potential depends on the nuclear density of the medium may also source a long-range force between dense stars [212]. This new long-range force sourced by the axion can be constrained by the measurement of the orbital decay of double pulsar or NS-pulsar binaries [212], Fig. 90.5. The gravitational wave signal of NS-NS mergers or black hole (BH) - NS mergers would also be modified by these axionic long-range forces [212, 213]. A corresponding bound [214] exploiting the gravitational waves observation from the binary NS inspiral GW170817 detected by LIGO (Laser Interferometer Gravitational-Wave Observatory) and Virgo [216] is also plotted in Fig. 90.5.

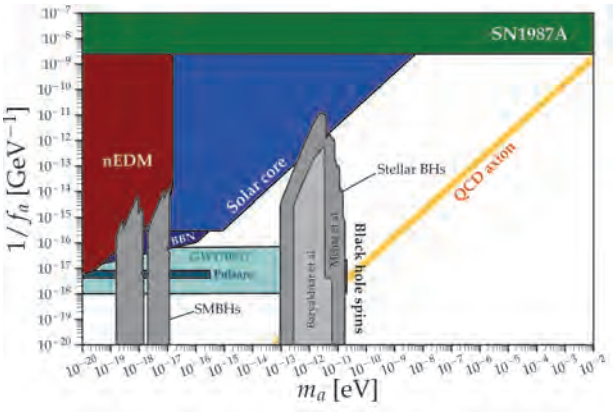

Figure 90.5: Exclusion plot for the QCD axion decay constant as described in the text. Figure courtesy of Ciaran O'Hare [31].

90.4.6 *Superradiance of black holes*

Light bosonic fields such as axions or ALPs can affect the dynamics and gravitational wave emission of rapidly rotating astrophysical BHs through the superradiance mechanism. When their Compton wavelength is of order of the size of the BH's ergoregion, they form gravitational bound states around the BH. Their occupation number grows exponentially by extracting energy and angular momentum from the black hole, forming a coherent axion or ALP bound state emitting gravitational waves. When accretion cannot replenish the spin of the BH, superradiance dominates the BH spin evolution; this is true for both supermassive and stellar mass BHs. The existence of destabilizing light bosonic fields thus leads to exclusion regions in the mass versus spin plot of rotating BHs. Stellar BH spin measurements exploiting well-studied binaries and two independent techniques exclude a mass range $6 \times 10^{-13}\,\mathrm{eV} < m_a < 2 \times 10^{-11}\,\mathrm{eV}$ at $2\,\sigma$, which for the axion excludes $3 \times 10^{17}\,\mathrm{GeV} < f_a < 1 \times 10^{19}\,\mathrm{GeV}$ [12, 217, 218]. These bounds apply when gravitational interactions dominate over the axion self-interaction, which is true for the QCD axion in this mass range. Mehta *et al.* [219, 220] considered superradiance bounds for string theory ALPs with a quartic self-coupling (of either sign) given by $\lambda = m_a^2/f_a^2$, using the bosenova model of Ref. [218]. The analysis can be recast into 95% confidence excluded regions in the plane (m_a, f_a) for ALPs, and are shown in Fig. 90.5 (also compiled in Ref. [45]). These bounds were further extended to massive vector and tensor fields in Ref. [221]. Baryakhtar *et al.* [222] used a more advanced model for the effect of self-interactions on superradiant evolution, and a different (frequentist) statistical methodology, leading to more conservative bounds from stellar mass BHs (region near 10^{-12} eV), see Fig. 90.5. Baryakhtar *et al.* [222] vetoed supermassive BHs (SMBHs) with spins measured at low significance, and thus show no bounds in the SMBH region (near 10^{-18} eV); Mehta *et al.* [219–221] included SMBHs in a (quasi-)Bayesian analysis with a flat prior on the spin.

Long lasting, monochromatic gravitational wave signals, which can be distinguished from ordinary astrophysical sources by their clustering in a narrow frequency range, are expected to be produced by axions or ALPs annihilating to gravitons. Gravitational waves could also be sourced by axions/ALPs transitioning between gravitationally bound levels. Accordingly, the gravitational wave detector Advanced LIGO should be sensitive to the axion in the $m_a \lesssim 10^{-10}\,\mathrm{eV}$ region. LIGO measurements of BH spins in binary merger events could also provide statistical evidence for the presence of an axion [223, 224]. Similar signatures could arise for supermassive and intermediate mass BHs for particles with masses $\lesssim 10^{-15}\,\mathrm{eV}$. Gravitational waves from such sources could be detected at lower-frequency observatories such as LISA (Laser Interferometer Space Antenna).

90.5 Cosmic Axions

90.5.1 *Cosmic axion populations*

There are two distinct populations of cosmic relic axion popoulations: a non-thermal one behaving as CDM, and a thermal one comprising a HDM component, in analogy to massive neutrinos. For $m_a \lesssim 0.01\,\mathrm{eV}$, thermal axions are dominantly produced by processes involving quarks and gluons [225, 226], while, for larger masses, the dominant thermalization process is $\pi + \pi \leftrightarrow \pi + a$ [51, 227, 228]. A number of evaluations exploiting cosmological precision data have found restrictive constraints on a possible HDM fraction that translate into an upper bound on the axion mass, $m_a \lesssim 1$ eV, if a LO axion-pion chiral effective field theory (EFT) analysis of the axion-pion thermalization rate is used [229–232]. Recently, it was found that the NLO contribution exceeds the LO contributions for masses below $m_a \lesssim 1.2\,(0.12/C_{a\pi})\,\mathrm{eV}$ [233]. Therefore, in order to assess the reach in sensitivity of future cosmological data sets, one has to improve the EFT description or to compute axion-pion scattering via lattice QCD techniques.

For $m_a \gtrsim 20$ eV, axions decay fast on a cosmic time scale, see Eq. (90.8), removing the axion population while injecting photons. This excess radiation provides additional limits on the axion- or ALP-photon coupling up to very large masses masses [234, 235]. In fact, photons from ALP decays could show up as peaks above known backgrounds in galactic x-ray spectra, could contribute to the extragalactic background light (EBL), could ionize primordial hydrogen and thus contribute to the optical depth after recombination, could spoil the agreement of big bang nucleosynthesis (BBN) with observations. The corresponding up-to-date bounds from Refs. [236, 237] are displayed in Fig. 90.2.

The main cosmological interest in axions derives from their possible role as CDM. In addition to thermal processes, axions are abundantly produced by the misalignment (MIS) mechanism [238–240].

The axion DM abundance crucially depends on the cosmological history. Let us first consider the so called *pre-inflationary PQ symmetry breaking scenario*, in which the PQ symmetry is broken before and during inflation and not restored afterwards. After the breakdown of the PQ symmetry, the axion field relaxes somewhere in the bottom of the "wine-bottle-bottom" potential. Near the QCD epoch, topological fluctuations of the gluon fields such as instantons explicitly break the PQ symmetry. This tilting of the "wine-bottle-bottom" drives the axion field toward the CP-conserving minimum, thereby exciting coherent oscillations of the axion field that ultimately represent a condensate of CDM. The fractional cosmic mass density in this homogeneous field mode, created by the MIS mechanism, is [30, 241–243],

$$\begin{aligned}\Omega_a^{\rm MIS}h^2 &\approx 0.12\left(\frac{f_a}{9\times10^{11}\ {\rm GeV}}\right)^{1.165} F\,\Theta_{\rm i}^2\\ &\approx 0.12\left(\frac{6\ \mu{\rm eV}}{m_a}\right)^{1.165} F\,\Theta_{\rm i}^2\,,\end{aligned} \tag{90.29}$$

where h is the present-day Hubble expansion parameter in units of 100 km s^{-1} Mpc^{-1}, and $-\pi \le \Theta_{\rm i} \le \pi$ is the initial "misalignment angle" relative to the CP-conserving position attained in the causally connected region which evolved into today's observable Universe. $F = F(\Theta_{\rm i}, f_a)$ is a factor accounting for anharmonicities in the axion potential. For $F\Theta_{\rm i}^2 = \mathcal{O}(1)$, m_a should be above $\sim 6\,\mu$eV in order that the cosmic axion density does not exceed the observed CDM density, $\Omega_{\rm CDM}h^2 = 0.12$. However, much smaller axion masses (much higher PQ scales) are still possible if entropy is diluted for example by the late decay of a scalar condensate (see for example [244] and references therein) or the initial value $\Theta_{\rm i}$ just happens to be small enough in today's observable Universe ("anthropic axion window" [245]). In the latter cosmological scenario, however, quantum fluctuations of the axion field during inflation are expected to lead to isocurvature density fluctuations which get imprinted to the temperature fluctuations of the CMB [246,247]. Their non-observation puts severe constraints on the Hubble expansion rate H_I during inflation [248–253], which read, in the simplest cosmological inflationary scenario,

$$H_I \lesssim 5.7\times10^8\ {\rm GeV}\left(\frac{5\ {\rm neV}}{m_a}\right)^{0.4175}, \tag{90.30}$$

if axions represent all of DM. In Ref. [254] an alternative to the MIS mechanism was proposed: the so-called kinetic MIS mechanism. In this case, the axion field is assumed to have an initial velocity which may be generated e.g. by a hypothesized explicit breaking of the axion shift symmetry in the early universe. The amount of QCD axion dark matter generated by the kinetic MIS mechanism can fit the observed dark matter abundance for any $f_a \lesssim 1.5\times10^{11}$ GeV, down to the minimum value allowed by the SN 1987A constraint.

In the *post-inflationary PQ symmetry breaking scenario*, on the other hand, $\Theta_{\rm i}$ will take on different values in different patches of the present Universe. The average contribution is [30, 241–243]

$$\Omega_a^{\rm MIS}h^2 \approx 0.12\left(\frac{30\ \mu{\rm eV}}{m_a}\right)^{1.165}. \tag{90.31}$$

The decay of cosmic strings and domain walls gives rise to a further population of CDM axions, whose abundance suffers from significant uncertainties [242, 243, 255–267] which arise from the difficulty in understanding the energy loss process of topological defects and the generated axion spectrum in a quantitative way. In fact, in the present state-of-the-art it is still possible that the CDM contribution from the decay of topological defects is subdominant [260] or overwhelmingly large [264] in comparison to the one from the MIS mechanism. Correspondingly, the plausible range of axion masses providing all of CDM in scenarios with postinflationary PQ symmetry breaking is still rather large, namely [260, 264]

$$m_a \approx 26\ \mu{\rm eV} - 0.5\ {\rm meV}, \tag{90.32}$$

for models with short-lived (requiring unit color anomaly $N = 1$) domain walls, such as the KSVZ model. For models with long-lived ($N > 1$) domain walls, such as an accidental DFSZ model [268], where the PQ symmetry is broken by higher dimensional Planck suppressed operators, the mass is predicted to be significantly higher [152, 259, 268, 269],

$$m_a \approx (0.58 - 130)\ {\rm meV}\,. \tag{90.33}$$

However, the upper part of the predicted range is in conflict with stellar energy-loss limits on the axion.

In this post-inflationary PQ symmetry breakdown scenario, the spatial axion density variations are large at the QCD transition, and they are not erased by free streaming. Gravitationally bound "axion miniclusters" form before and around matter-radiation equality [270–272]. A significant fraction of CDM axions can reside in these bound objects [262, 273]. Remarkably, the minicluster fraction can be bounded by gravitational lensing [274–276], although more simulations are required to understand whether miniclusters are dense enough and survive in sufficient quantities for lensing bounds to apply.

In the above predictions of the fractional cosmic mass density in axions, the exponent, 1.165, arises from the non-trivial temperature dependence of the topological susceptibility $\chi(T) = m_A^2(T)f_A^2$ at temperatures slighty above the QCD quark-hadron phase transition. Lattice QCD calculations of this exponent [30, 277–281], but also Ref. [282], found it to be remarkably close to the prediction of the dilute instanton gas approximation [283] which was previously exploited. Therefore, the state-of-the-art prediction of the axion mass relevant for DM for a fixed initial misalignment angle $\Theta_{\rm i}$ differs from the previous prediction by just a factor of order one.

The non-thermal production mechanisms attributed to axions are generic to light bosonic weakly interacting particles such as ALPs [17]. The relic abundance is set by the epoch when the axion mass becomes significant, $3H(t) \approx m_a(t)$, and ALP field oscillations begin. For ALPs to contribute to the DM density this epoch must precede that of matter radiation equality. For a temperature independent ALP mass this leads to the bound:

$$m_a \gtrsim 7\times10^{-28}\ {\rm eV}\left(\frac{\Omega_m\,h^2}{0.15}\right)^{1/2}\left(\frac{1+z_{\rm eq}}{3.4\times10^3}\right)^{3/2}. \tag{90.34}$$

ALPs lighter than this bound are allowed if their cosmic energy density is small, but they are quite distinct from other forms of DM [284]. Ignoring anharmonicities in the ALP potential, and taking the ALP mass to be temperature independent, the relic density in DM ALPs due to the MIS mechanism is given by

$$\begin{aligned}\Omega_{\rm ALP}^{\rm MIS}h^2 =& 0.12\left(\frac{m_a}{4.7\times10^{-19}\,{\rm eV}}\right)^{1/2}\left(\frac{f_a}{10^{16}\,{\rm GeV}}\right)^2\times\\ &\left(\frac{\Omega_m h^2}{0.15}\right)^{3/4}\left(\frac{1+z_{\rm eq}}{3.4\times10^3}\right)^{-3/4}\Theta_{\rm i}^2\,.\end{aligned} \tag{90.35}$$

An ALP decay constant near the GUT scale gives the correct relic abundance for *ultralight ALPs* (ULAs) with $m_{\rm ULA} \approx 10^{-19}$ eV [285, 286]. ULAs encompass the entire Earth in a single Compton wavelength, and for large occupation numbers are modelled as a coherent classical field. The coherence time is determined by the mass and virial velocity in the Milky Way, $\tau_{\rm coh} \sim 1/m_{\rm ULA}v_{\rm vir}^2$, with the detailed properties described by a stochastic model with an approximately Rayleigh Jeans distribution [287]. Natural models for ULAs can be found in string and M-theory compactifications [8–15], in field theory with accidental symmetries [288, 289], or new hidden strongly coupled sectors [290, 291].

In addition to the gravitational potential energy, the ULA field also carries gradient energy. On scales where the gradient energy is non-negligible, ULAs acquire an effective pressure and do not behave as CDM. The gradient energy opposes gravitational collapse, leading to a Jeans scale below which perturbations are stable [292]. The Jeans scale suppresses linear cosmological structure formation relative to CDM [293–295]. The Jeans scale at matter-radiation equality in the case that ULAs make up all of

CDM is:

$$k_{\rm J,eq} = 8.7\,{\rm Mpc}^{-1}\left(\frac{1+z_{\rm eq}}{3.4\times10^3}\right)^{-1/4}\left(\frac{h^2\Omega_{\rm ALP}^{\rm MIS}}{0.12}\right)^{1/4}\times\left(\frac{m_{\rm ULA}}{10^{-22}\,{\rm eV}}\right)^{1/2}. \quad (90.36)$$

On non-linear scales the gradient energy leads to the existence of a class of pseudo-solitons known as oscillatons, or axion stars [296]. Axion stars are expected to form in all cosmological scenarios, and for all types of ALPs, including the QCD axion [297–299].

Cosmological and astrophysical observations are consistent with the CDM model, and departures from it are only allowed on the scales of the smallest observed DM structures with $M \sim 10^{6-8} M_\odot$. The CMB power spectrum and galaxy autocorrelation power spectrum limit the ULA mass to $m_{\rm ULA} \gtrsim \mathcal{O}({\rm few}) \times 10^{-24}$ eV from linear theory of structure formation [284, 300]. Analytic models [301] and N-body simulations [302] for non-linear structures show that halo formation is suppressed in ULA models relative to CDM. This leads to constraints on the ULA mass of $m_{\rm ULA} > 10^{-22}\,{\rm eV}$ from observations of high-z galaxies [302–304], and $m_{\rm ULA} > 2\times10^{-20}$ eV from the Lyman-alpha forest flux power spectrum [305]. Including the effects of anharmonicities on structure formation with ALPs can weaken these bounds if the misalignment angle $\Theta_{\rm i} \approx \pi$ [306]. A comprehensive study of Milky Way satellites by the DES collaboration resulted in the bound $m_{\rm ULA} > 2.9\times10^{-21}$ eV [307]. Cosmological simulations that treat gradient energy in the ULA field beyond the N-body approximation have just recently become available [297, 308–310], and show, among other things, evidence for the formation of axion stars in the centres of ULA halos (various consequences of axion stars are considered in Refs. [311]). These central axion stars have been conjectured to play a role in the apparently cored density profiles of dwarf spheroidal galaxies, and other central galactic regions [297, 312–317]. However, the relationship between the halo mass and the axion star mass [318] leads to problems with this scenario in some galaxies [319–321]. It should be emphasised that many of the conclusions about the role of ULA axion stars in galactic dynamics are based on use of simulation results that do not contain baryons and feedback could be important [322–324].

Inside DM halos the axion gradient energy causes coherence on the de Broglie wavelength and fluctuations on the coherence time [297,325]. These fluctuations can be thought of as short-lived quasiparticles and lead to relaxation processes that can be described statistically [286,326] (this relaxation processes also leads to the gravitational condensation of axion stars [298]). The typical relaxation time is:

$$t \sim 10^{10}\ {\rm years}\left(\frac{m_{\rm ULA}}{10^{-22}\ {\rm eV}}\right)^3\left(\frac{v}{100\ {\rm km\ s^{-1}}}\right)^2\left(\frac{r}{5\ {\rm kpc}}\right)^4, \quad (90.37)$$

where v and r are the velocity and radius of the orbit in the host DM halo.

Relaxation processes such as these are not observed in galaxies, though there are some circumstances where they may be desirable [286]. An absence of observed relaxation can be used to set limits on the ULA mass. An absence of Milky Way disk thickening excludes $m_{\rm ULA} > 0.6\times10^{-22}$ eV [327], while stellar streams give the stronger bound $m_{\rm ULA} > 1.5\times10^{-22}$ eV [328]. The survival of the old star cluster in Eridanus II [329] excludes the range of masses 10^{-21} eV $\lesssim m_{\rm ULA} \lesssim 10^{-19}$ eV [330]. As in the case of ULA axion stars, current constraints from heating do not fully account for the possible role of baryons.

Finally, one should note that the beyond-CDM physics of ULAs (Jeans scale, relaxation, axion star formation) of course also applies to the QCD axion on smaller length scales. This is of particular interest inside axion miniclusters [270, 271, 298, 299].

90.5.2 *Electron recoil searches*

In a DM direct detection experiment, a DM ALP featuring a coupling to the electron can be absorbed by the target material, leading to a mono-energetic electronic recoil signal peaked at m_a. This mechanism allowed the EDELWEISS [331], PandaX [332], SuperCDMS [333] and XENON1T [334] collaborations to put the bounds on the axion-electron coupling displayed in Fig. 90.3 in the keV mass range.

90.5.3 *Telescope searches*

The two-photon decay is extremely slow for axions with masses in the CDM regime, but could be detectable for eV masses. The signature would be a quasi-monochromatic emission line from galaxies and galaxy clusters. The expected optical line intensity for DFSZ axions is similar to the continuum night emission. A search for optical line emission in two Abell clusters using spectra from the VIMOS (Visible Multi-Object Spectrograph) integral field unit at the Very Large Telescope (VLT) excludes axions and ALPs with a two photon coupling bigger than $\sim 5\times10^{-12}\,{\rm GeV}^{-1}$ in the mass range between 4.5 and 5.5 eV, see Fig. 90.2. Spectral data on the dwarf spheroidal galaxy Leo T from the Multi Unit Spectroscopic Explorer (MUSE) at the VLT improve these constraints by more than an order of magnitude for ALP masses between 2.7 and 5.3 eV [335], see Fig. 90.2.

Very low-mass axions in halos produce a weak quasi-monochromatic radio line. Virial velocities in undisrupted dwarf galaxies are very low, and the axion decay line would therefore be extremely narrow. A search with the Haystack radio telescope on three nearby dwarf galaxies provided a limit $|g_{a\gamma\gamma}| < 1.0\times10^{-9}\,{\rm GeV}^{-1}$ at 96% CL for $298 < m_a < 363\ \mu$eV [336]. However, this combination of m_a and $g_{a\gamma\gamma}$ does not exclude plausible axion models.

A monochromatic signal is also produced in the conversion of DM axions in the background of slowly varying galactic B-fields [337]. The signal is, however, sensitive to magnetic field power on the scale of the axion mass [338]. Present and future radio telescopes appear to be able to probe ALP DM in the mass range $0.1 - 100\ \mu$eV for couplings $g_{a\gamma\gamma} \gtrsim 10^{-13}\ {\rm GeV}^{-1}$ [338] – unfortunately not reaching down to the benchmark QCD axion sensitivity.

Resonant conversion of QCD axion or ALP DM in NS magnetospheres may give a detectable signal from individual NSs for axion masses in the μeV range [339]. Recent analyses of radio data in the frequency range 1-40 GHz from several NSs have found no evidence for a narrow peak predicted from this mechanism and therefore put bounds on the axion-photon coupling around $10^{-11}\,{\rm GeV}^{-2}$ for $4 \lesssim m_a \lesssim 160\,{\rm GHz}$ [340–342], see Fig. 90.2. However, these limits may still suffer from significant uncertainties because the line intensity is difficult to predict in detail in the complicated environments of NSs [342–345]. Stimulated ALP decays in high radiation environments may be detectable, by next-generation radio telescopes such as the Square Kilometer Array, down to $g_{a\gamma\gamma} \gtrsim 10^{-11}\,{\rm GeV}^{-1}$, for masses between μeV and 0.1 meV [346]. Furthermore, in condensed ALP dark matter structures such as ALP stars, a parametric instability may lead to an exponential enhancement of the photon flux from ALP-photon conversion by a factor $\sim \exp\left[|g_{a\gamma\gamma}|\int ds \rho_a^{1/2}(s)\right]$, where the integral is along any photon trajectory through the ALP overdensity [347, 348].

Photon propagation on an ULA DM background can induce birefringence that can be compared with upper limits from the CMB [349–351] and may also be probed with other sources such as pulsars [352].

90.5.4 *Microwave cavity experiments*

Over a large part of the plausible m_a range for CDM, Galactic halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q electromagnetic cavity permeated by a strong, static B field [7,353,354]. The cavity frequency is tunable, and the signal is maximized when the resonant frequency is the total axion energy, rest mass plus kinetic energy, of $\nu = (m_a/2\pi)\,[1 + \mathcal{O}(10^{-6})]$, the width above the rest mass representing the axions' virial distribution in the galaxy near Earth. The frequency spectrum may also contain finer structure from axions more recently fallen into the galactic potential and not yet completely virialized [355, 356] or otherwise incompletely thermalized.

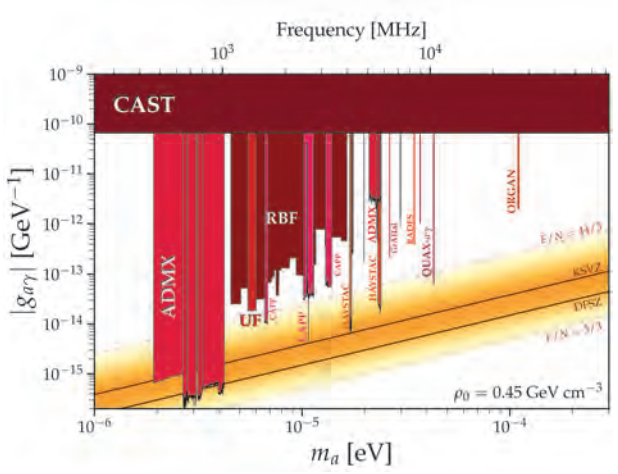

Figure 90.6: Exclusion plot for ALP-photon coupling with closeup on the parameter space of RF cavity experiments as described in the text. Figure courtesy of Ciaran O'Hare [31].

The feasibility of this technique was established in early experiments (RBF (Rochester-Brookhaven-Florida) and UF (University of Florida)) of relatively small sensitive volume, $\mathcal{O}(1$ liter), with HFET-based microwave amplifiers, setting limits in the range $4.5 < m_a < 16.3$ μeV [357–359], but lacking by 2–3 orders of magnitude the sensitivity required to detect realistic axions, see Fig. 90.6.

Later, the first generation of ADMX ($B \sim 8$ T, $V \sim 200$ liters) achieved sensitivity to KSVZ axions, assuming they saturate the local DM density and are well virialized, over the mass range 1.9–3.3 μeV [360]. Should halo axions have a significant narrow component not yet virialized, ADMX was sensitive to DFSZ axions over the entire mass range [361]. The corresponding 90% CL exclusion regions shown in Fig. 90.6 assume a local CDM density of 7.5×10^{-25} g cm^{-3} (450 MeV cm^{-3}).

Somewhat later, the ADMX experiment commissioned an upgrade [362] that replaced the microwave HFET amplifiers by near-quantum-limited low-noise dc SQUID microwave amplifiers [363] and, more recently, with Josephson parametric amplifiers (related to the earlier dc SQUID amplifiers), also with noise near-quantum-limited [364]. With its large volume and low noise, ADMX has achieved an unprecedented axion DM sensitivity in the mass range between 2.7 and 4.2 μeV [365–368], down to the DFSZ benchmark axion-photon coupling over much of the range, see Fig. 90.6. This apparatus is also sensitive to certain other hypothetical light bosons, such as hidden photons or chameleons, over a limited parameter space [17, 369, 370].

ADMX also deployed a testbed experiment to probe higher masses. This experiment – ADMX-Sidecar – sharing the magnet bore and operating in tandem with the main ADMX experiment, searches in three widely spaced frequency ranges (4202–4249 MHz, 5086–5799 MHz and 7173–7203 MHz), using both the TM_{010} and TM_{020} cavity modes, and demonstrating the use of a piezoelectric actuator for cavity tuning in the high-vacuum, high magnetic field, cryogenic environment [371].

The HAYSTAC experiment reported results from a microwave cavity search for DM axions with masses above 20 μeV. They exclude axions with two-photon coupling $|g_{a\gamma\gamma}| \gtrsim 2 \times 10^{-14}$ GeV^{-1} over the range $23.15\,\mu\text{eV} < m_a < 24.0\,\mu\text{eV}$ [372, 373], a factor of 2.7 above the KSVZ coupling benchmark, see Fig. 90.6. With a Josephson parametric amplifier, this experiment has demonstrated system noise approaching the "standard quantum limit" for the first time in an axion search. More recently, HAYSTAC explored state squeezing to reduce the system noise, where the squeezed quadrature had lower noise relative to that of the "standard quantum limit", thereby reducing the scan time by a factor of around 2 over a narrow mass range. This resulted in limits on $|g_{a\gamma\gamma}|$ about a factor of 1.4 above the KSVZ benchmark coupling over the axion-mass ranges $16.96\,\mu\text{eV} < m_a < 17.12.\,\mu\text{eV}$ and $17.14\,\mu\text{eV} < m_a < 17.28\,\mu\text{eV}$ at 90% CL [374] as shown in Fig. 90.6.

The ORGAN experiment aims to probe axions over the relatively high-mass range $60\,\mu\text{eV} < m_a < 210\,\mu\text{eV}$, which includes axion masses motivated by postinflationary PQ symmetry breaking. ORGAN is based on long, thin cavities with this early generation not being tunable and operating in the TM_{020} mode. In this pathfinding run, it set the limit $|g_{a\gamma\gamma}| < 2 \times 10^{-12}$ GeV^{-1} at 110 μeV across a narrow mass range 2.5 neV [375], see Fig. 90.6. Another non-tunable experiment is QUAX a-γ, a haloscope of otherwise conventional design sensitivity a factor of approximately 5 above the benchmark KSVZ coupling at two narrowband ranges near 10 GHz [376, 377], see Fig. 90.6. Other cavity detectors are moving into operation, including an experiment with unusual high-aspect-ratio cavities in the CAST bore (CAST-RADES [378]).

CAPP is an ambitious program to search for axions across a wide mass range at high sensitivity. Recently the CAPP-8TB detector has reported results approaching KSVZ sensitivity in the mass range 6.62–8.82 μeV [379]. A further refinement is searching the higher frequencies allowed by subdividing a cavity into smaller higher-frequency cells. Such a multi-cell cavity system has reported sensitivity around an order-of-magnitude above the KSVZ benchmark coupling in the mass range 13.0–13.9 μeV [380], see Fig. 90.6. The CAPP-PACE detector has reported limits around KSVZ benchmark sensitivity in the mass range 10.7126–10.7186 μeV and around an order-of-magnitude above benchmark KSVZ coupling in the mass range 10.16–10.37 [381], see Fig. 90.6.

90.5.5 *New concepts for axion DM direct detection*

Other new concepts for searching for axion DM are also being investigated. An alternative to the microwave cavity technique is based on a novel detector architecture consisting of an open, Fabry-Perot resonator and a series of current-carrying wire planes [382]. The Orpheus detector has demonstrated this new technique, excluding DM ALPs with masses between 68.2 and 76.5 μeV and axion-photon couplings greater than 4×10^{-7} GeV^{-1}. This technique may be able to probe DM axions in the mass range from 40 to 700 μeV. "Plasma haloscopes" are under development by the ALPHA collaboration [383]. This concept uses a metamaterial consisting of spaced out wires, inducing an effective photon mass, tunable with wire separation, and sensitive to axion masses 35–400 μeV. Another detector concept exploits the fact that a magnetized mirror would radiate photons in the background of axion DM, which could be collected like in a dish antenna [384]. The proposed MADMAX experiment will place a stack of dielectric layers in a magnetic field in order to resonantly enhance the photon signal, aiming a sensitivity to probe the mass range $40\,\mu\text{eV} \lesssim m_a \lesssim 200\,\mu\text{eV}$ [385, 386]. Optical dielectric haloscopes with single photon signal detection have been proposed to search for axions in the 50 meV – 10 eV mass range [387]. Absorption of axions on molecular transitions can be sensitive to the axion pseudoscalar coupling g_{aNN} to nucleons or the pseudoscalar coupling g_{aee} to electrons in the 0.5 – 20 eV range [388]. It has also been pointed out that the coupling induced by an axion field between photonic modes [389, 390] or atomic states [391] separated by an energy equal to the axion mass may be leveraged for axion detection, though the implementation may be challenging. Certain magnetic topological insulators are conjectured to contain axion-polaritons, quasiparticles composed of magnons and the electric field, with magnetically tunable mass in the meV to eV range [392–394]. Axion dark matter leads to resonant photon emission from such materials, which can be detected [395, 396].

In the intermediate mass region, $\text{neV} \lesssim m_a \lesssim 0.1\,\mu\text{eV}$, one may exploit a cooled LC circuit and precision magnetometry to search for the oscillating electric current induced by DM axions in a strong magnetic field [397, 398]. A number of small-scale pathfinder experiments have implemented this approach: ABRACADABRA [399, 400] used a nonresonant configuration in a toroidal magnet for a broadband search, ADMX-SLIC [401] used a resonant configuration in a solenoid magnet for a narrowband search, SHAFT [402] used a nonresonant configuration in a toroidal magnet enhanced with a ferromagnetic core, and BASE [403] used antiprotons in a Penning trap as the LC cir-

cuit. The exclusion limits from these experiments are shown in Fig. 90.2; none are yet sensitive to the QCD axion. Future work in this direction is expected to have much more competitive limits [404].

The oscillating Galactic DM axion field induces oscillating nuclear electric dipole moments (EDMs) [139],

$$d_N(t) = g_{aN\gamma}\,\sqrt{2\rho_{a\mathrm{DM}}}\cos(m_a\,t)/m_a\,, \tag{90.38}$$

where $g_{aN\gamma}$ is the coupling of the axion to the nucleon EDM operator, defined in Eq. (90.4). An analysis of the ratio of spin-precession frequencies of stored ultracold neutrons and ^{199}Hg atoms measured by neutron EDM experiments for an axion-induced oscillating neutron EDM revealed no signal consistent with axion DM, excluding a sizeable region of parameter space in the mass region $10^{-24}\,\mathrm{eV} \leq m_a \leq 10^{-17}\,\mathrm{eV}$ [405], which surpass the limits on anomalous energy loss of SN 1987A by more than seven orders of magnitude, see Fig. 90.1, and are competitive with the ones from the requirement of successful BBN established in [406], see Fig. 90.5.[1] In fact, the oscillating dark matter axion field could increase the neutron-proton mass difference at neutron freeze-out and thus result in the underproduction of ^{4}He during BBN. The oscillating EDMs cause also the precession of nuclear spins in a nucleon spin polarized sample in the presence of an electric field. The resulting transverse magnetization can be searched for by exploiting magnetic-resonance (MR) techniques, which are most sensitive in the range of low oscillation frequencies corresponding to sub-neV axion masses. The aim of the corresponding Cosmic Axion Spin Precession Experiment (CASPEr) [407] is to probe axion DM in the anthropic window, $f_a \gtrsim 10^{15}\,\mathrm{GeV}$ ($m_a \lesssim$ neV), motivated from Grand Unification [408–411]. There are two interactions probed through MR: the electric dipole coupling as searched for by CASPEr-electric, whose first run has established the limits shown in Fig. 90.1 [412], and an interaction between the axion field gradient and the nuclear spin, which is aimed for by CASPEr-wind. In the meantime, the latter has been explored through comagnetometry between a variety of nuclei: H-^{12}C in CASPEr-ZULF [413,414], Xe-Rb in NASDUCK [415], and K-^{3}He [416,417]. The exclusions from these searches are shown in Fig. 90.4. Sub-μeV ALP masses can also be probed by using the storage ring EDM method proposed in Ref. [418] which exploits a combination of B and E-fields to produce a resonance between the $g-2$ spin precession frequency and the DM ALP field oscillation frequency. This method, however, does not reach the sensitivity to probe the QCD axion prediction for $g_{aN\gamma}$. An eventually non-zero axion electron coupling g_{aee} will lead to an electron spin precession about the axion DM wind [419, 420]. The QUAX a-e experiment exploits MR inside a magnetized material [421]. Because of the higher Larmor frequency of the electron, it is sensitive in the classic window. Its first run established the bound in the mass range 42.4 to 43.2 μeV [422], slightly better than the solar ν bound, shown in Fig. 90.3.

90.6 Conclusions

There is a strengthening physics case for very weakly coupled light particles beyond the Standard Model. The elegant solution of the strong CP problem proposed by Peccei and Quinn yields a particularly strong motivation for the axion. In many theoretically appealing ultraviolet completions of the Standard Model axions and ALPs occur automatically. Moreover, they are natural CDM candidates. Perhaps the first hints of their existence have already been seen in the anomalous excessive cooling of stars and the anomalous transparency of the Universe for very high energy gamma rays. Interestingly, a significant portion of previously unexplored, but phenomenologically very interesting and theoretically very well motivated axion and ALP parameter space can be tackled in the foreseeable future by a number of terrestrial experiments searching for axion/ALP DM, for solar axions/ALPs, and for light apparently shining through a wall.

[1] These limits are still to the left of the canonical QCD axion line. However, in non-minimal models where the QCD axion is a mediator between strongly interacting hidden sectors enjoying a discrete, $\mathbb{Z}_{\mathcal{N}}$, shift symmetry, the QCD axion line can be shifted to the left in discrete steps, without any fine tuning [44, 45, 291].

90.7 Acknowledgements

It is a pleasure to thank Masha Baryakhtar, Francesca Calore, Luca Di Luzio, Andrew Geraci, Maurizio Giannotti, Igor Irastorza, David J.E. Marsh, Alessandro Mirizzi, Benjamin Safdi, Ken'ichi Saikawa, Yannis Semertzidis, Guenter Sigl, and Sergey Troitsky for discussions, suggestions, and comments on this review. Particular thanks to Ciaran O'Hare for maintaining a publicly accessible collection of axion plots and providing updates to accomodate this review [31].

91. Searches for Quark and Lepton Compositeness

Revised October 2021 by K. Hikasa (Tohoku U.), M. Tanabashi (Nagoya U.; KMI, Nagoya U.), K. Terashi (ICEPP, Tokyo U.) and N. Varelas (U. of Illinois at Chicago).

91.1 Limits on contact interactions

If quarks and leptons are made of constituents, then at the scale of constituent binding energies (compositeness scale) there should appear new interactions among them. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ. The dominant effect of the compositeness of fermion ψ should come from the lowest dimensional interactions with four fermions (contact terms), whose most general flavor-diagonal color-singlet chirally invariant form reads [1, 2]

$$\mathcal{L} = \mathcal{L}_{LL} + \mathcal{L}_{RR} + \mathcal{L}_{LR} + \mathcal{L}_{RL},$$

with

$$\mathcal{L}_{LL} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{LL} (\bar\psi^i_L \gamma_\mu \psi^i_L)(\bar\psi^j_L \gamma^\mu \psi^j_L),$$

$$\mathcal{L}_{RR} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{RR} (\bar\psi^i_R \gamma_\mu \psi^i_R)(\bar\psi^j_R \gamma^\mu \psi^j_R),$$

$$\mathcal{L}_{LR} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{LR} (\bar\psi^i_L \gamma_\mu \psi^i_L)(\bar\psi^j_R \gamma^\mu \psi^j_R),$$

$$\mathcal{L}_{RL} = \frac{g^2_{\rm contact}}{2\Lambda^2} \sum_{i,j} \eta^{ij}_{RL} (\bar\psi^i_R \gamma_\mu \psi^i_R)(\bar\psi^j_L \gamma^\mu \psi^j_L), \qquad (91.1)$$

where i, j are the indices of fermion species. Color and other indices are suppressed in Eq. (91.1). Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ. Note $\eta^{ij}_{\alpha\beta} = \eta^{ji}_{\beta\alpha}$. Therefore, in order to specify the contact interaction among the same fermion species $i = j$, it is enough to use η_{LL}, η_{RR} and η_{LR}. We will suppress the indices of fermion species hereafter. We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2_{\rm contact}/4\pi = g^2_{\rm contact}(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{aligned}
&\Lambda = \Lambda^\pm_{LL} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1,\ 0,\ 0)\ , \\
&\Lambda = \Lambda^\pm_{RR} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0,\ \pm 1,\ 0)\ , \\
&\Lambda = \Lambda^\pm_{VV} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1,\ \pm 1,\ \pm 1)\ , \\
&\Lambda = \Lambda^\pm_{AA} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (\pm 1,\ \pm 1,\ \mp 1)\ , \\
&\Lambda = \Lambda^\pm_{V-A} \quad \text{for} \quad (\eta_{LL}, \eta_{RR}, \eta_{LR}) = (0,\ 0,\ \pm 1)\ . \qquad (91.2)
\end{aligned}$$

Such interactions can arise by interchanging constituents (when the fermions have common constituents), and/or by exchanging the binding quanta (whenever binding quanta couple to constituents of both particles).

Fermion scattering amplitude induced from the contact interaction in Eq. (91.1) interferes with the Standard Model (SM) amplitude destructively or constructively [2]. The sign of interference depends on the sign of $\eta_{\alpha\beta}$ ($\alpha, \beta = L, R$). For instance, in the parton level $qq \to qq$ scattering cross section in the $\Lambda^\pm_{LL}$ model, the contact interaction amplitude and the SM gluon exchange amplitude interfere destructively for $\eta_{LL} = +1$, while they interfere constructively for $\eta_{LL} = -1$. In models of quark compositeness, the quark scattering cross sections induced from the contact interactions receive sizable QCD radiative corrections. Ref. [3] provides the exact next-to-leading order (NLO) QCD corrections to the contact interaction induced quark scattering cross sections.

Over the last three decades experiments at the CERN Sp$\bar{\rm p}$S [4, 5], the Fermilab Tevatron [6, 7], and the CERN LHC [8–12] have searched for quark contact interactions, characterized by the four-fermion effective Lagrangian in Eq. (91.1), using jet final states. These searches have been performed primarily by studying the angular distribution of the two highest transverse momentum, $p_{\rm T}$, jets (dijets), and the inclusive jet $p_{\rm T}$ spectrum. The variable $\chi = \exp(|(y_1 - y_2)|)$ is used to measure the dijet angular distribution, where y_1 and y_2 are the rapidities of the two jets with the highest transverse momenta. For collinear massless parton scattering, χ is related to the polar scattering angle θ^* in the partonic center-of-mass frame by $\chi = (1+|\cos\theta^*|)/(1-|\cos\theta^*|)$. The choice of χ is motivated by the fact that the angular distribution for Rutherford scattering, which is proportional to $1/(1-\cos\theta^*)^2$, is independent of χ. In perturbative QCD the χ distributions are relatively uniform and only mildly modified by higher-order QCD or electroweak corrections. Signatures of quark contact interactions exhibit more isotropic angular distribution than QCD and can be identified as an excess at low values of χ. In the inclusive jet cross section measurement, quark contact interaction effects are searched for as deviations from the predictions of perturbative QCD in the tails of the high-$p_{\rm T}$ jet spectrum [11].

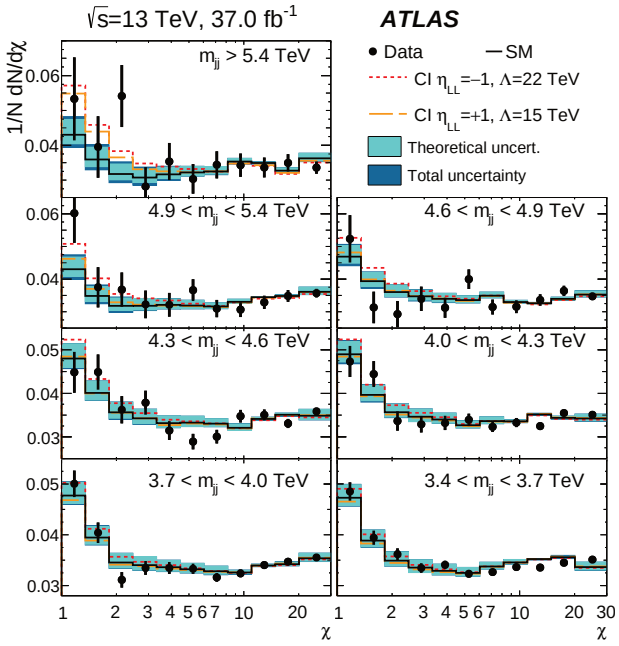

Figure 91.1: Normalized dijet angular distributions in several dijet mass (m_{jj}) ranges. The data distributions are compared to PYTHIA8 predictions with NLO and electroweak corrections applied (solid line) and with the predictions including a contact interaction (CI) term in which only left-handed quarks participate of compositeness scale $\Lambda^+_{LL} = 15$ TeV (dashed line) and $\Lambda^-_{LL} = 22$ TeV (dotted line). The theoretical uncertainties and the total theoretical and experimental uncertainties in the predictions are displayed as shaded bands around the SM prediction. Figure adopted from Ref. [9].

Recent results from the LHC, using data collected at proton-proton center-of-mass energy of $\sqrt{s} = 13$ TeV, extend previous limits on quark contact interactions. Figure 91.1 shows the normalized dijet angular distributions for several dijet mass ranges measured in ATLAS [9] at $\sqrt{s} = 13$ TeV. The data distributions are compared with SM predictions, estimated using PYTHIA8 [13] with GEANT4-based [14] ATLAS detector simulation and corrected to NLO QCD calculation provided by NLO Jet++ [15] including electroweak corrections [16], and with predictions including a contact interaction term in which only left-handed quarks participate at compositeness scale $\Lambda^+_{LL} = 15$ TeV ($\Lambda^-_{LL} = 22$ TeV) with destructive (constructive) interference. Over a wide range of χ and dijet mass the data are well described by the SM predictions. Using the dijet angular distributions measured at high dijet masses and $\sqrt{s} = 13$ TeV, the ATLAS [9] and CMS [12] Collaborations have set 95% confidence level (C.L.) lower limits on the contact interaction scale Λ, ranging

from 9.2 to 29.5 TeV for different quark contact interaction models that correspond to various combinations of (η_{LL}, η_{RR}, η_{LR}), as summarized in Figure 91.2. The contact interaction scale limits extracted using the dijet angular distributions include the exact NLO QCD corrections to dijet production induced by contact interactions [3]. In proton-proton collisions, the $\Lambda^{\pm}_{LL}$ and $\Lambda^{\pm}_{RR}$ contact interaction models result in identical tree-level cross sections and NLO QCD corrections and yield the same exclusion limits. For $\Lambda^{\pm}_{VV}$ and $\Lambda^{\pm}_{AA}$, the contact interaction predictions are identical at tree level, but exhibit different NLO QCD corrections and yield different exclusion limits.

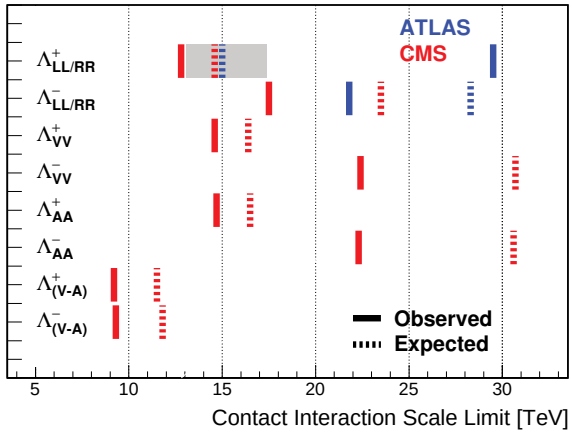

Figure 91.2: Observed (solid lines) and expected (dashed lines) 95% C.L. lower limits on the contact interaction scale Λ for different contact interaction models from ATLAS [9] and CMS [12] using the dijet angular distributions. The contact interaction models used for the dijet angular distributions include the exact NLO QCD corrections to dijet production. The shaded band for the $\Lambda^{+}_{LL/RR}$ model indicates the range of contact interaction scale that was not excluded in ATLAS [9], due to an observed excess in the data that produced a weaker limit.

If leptons (l) and quarks (q) are composite with common constituents, the interaction of these constituents will manifest itself in the form of a *llqq*-type four-fermion contact interaction Lagrangian at energies below the compositeness scale Λ. The *llqq* terms in the contact interaction Lagrangian can be expressed as

$$\mathcal{L}_{LL} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{LL} (\bar{q}^i_L \gamma_\mu q^i_L)(\bar{l}^j_L \gamma^\mu l^j_L),$$

$$\mathcal{L}_{RR} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{RR} (\bar{q}^i_R \gamma_\mu q^i_R)(\bar{l}^j_R \gamma^\mu l^j_R),$$

$$\mathcal{L}_{LR} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{LR} (\bar{q}^i_L \gamma_\mu q^i_L)(\bar{l}^j_R \gamma^\mu l^j_R),$$

$$\mathcal{L}_{RL} = \frac{g^2_{\rm contact}}{\Lambda^2} \sum_{i,j} \eta^{ij}_{RL} (\bar{q}^i_R \gamma_\mu q^i_R)(\bar{l}^j_L \gamma^\mu l^j_L). \qquad (91.3)$$

Searches on quark-lepton compositeness have been reported from experiments at LEP [17–20], HERA [21, 22], the Tevatron [23, 24], and recently from the ATLAS [25, 26] and CMS [27, 28] experiments at the LHC. The most stringent searches for *llqq* contact interactions are performed by the LHC experiments using high-mass oppositely-charged lepton pairs produced through the $q\bar{q} \to l^+l^-$ Drell-Yan process. The contact interaction amplitude of the $u\bar{u} \to l^+l^-$ process ($l = e$ or μ) interferes with the corresponding SM amplitude constructively (destructively) for $\eta^{ul}_{\alpha\beta} = -1$ ($\eta^{ul}_{\alpha\beta} = +1$). The ATLAS Collaboration has extracted limits on the *llqq* contact interaction at $\sqrt{s} = 13$ TeV for the right-right ($\eta_{RR} = \pm 1$, $\eta_{LL} = \eta_{LR} = \eta_{RL} = 0$), left-left ($\eta_{LL} = \pm 1$, $\eta_{RR} = \eta_{LR} = \eta_{RL} = 0$), and left-right ($\eta_{LR} = \eta_{RL} = \pm 1$, $\eta_{RR} = \eta_{LL} = 0$) models. In Ref. [26], ATLAS used a background estimate directly obtained from data. Combining the dielectron and dimuon channels, the 95% C.L. lower limits on the *llqq* contact interaction scale Λ are 36 TeV (27 TeV) for the right-right model, 36 TeV (26 TeV) for the left-left model, and 33 TeV (29 TeV) for the left-right model, each with constructive (destructive) interference [26]. The CMS Collaboration, using a 140 fb^{-1} dataset at 13 TeV, has set 95% C.L. exclusion limits on the *llqq* contact interaction scale that range from $\Lambda_{LL} > 23.9$ TeV for the destructive interference to $\Lambda_{RR} > 36.4$ TeV for the constructive interference, for the left-left and the right-right models, respectively [28].

Note that the contact interactions arising from the compositeness of quarks and leptons in Eq. (91.1) can also be regarded as a part of more general dimension six operators in the context of low energy standard model effective field theory (SMEFT). For a complete list of SM gauge invariant dimension six operators, see [29, 30]. A computation of the one loop anomalous dimension matrix for SMEFT operators are found in Refs. [31–33]. See also Refs. [34] and [35] for recent reviews. Consistent SMEFT reinterpretations of top-quark data, and high energy non-resonant dijet and dilepton data are provided, e.g., in Refs. [36–38].

Interactions of hypothetical dark matter candidate particles with SM particles through mediators can also be described as contact interactions at low energy. See *"Searches for WIMPs and Other Particles"* in this volume for limits on the interactions involving dark matter candidate particles.

91.2 Limits on excited fermions

Another typical consequence of compositeness is the appearance of excited leptons and quarks (l^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares a leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. The smallness of the lepton mass and the success of QED prediction for $g-2$ suggest chirality conservation, *i.e.,* an excited lepton should not couple to both left- and right-handed components of the corresponding lepton [39–41].

Excited leptons may be classified by $SU(2) \times U(1)$ quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \qquad [\nu^*_R], \qquad l^*_R.$$

   ν^*_R is necessary if we assume ν^* has a Dirac mass.

2. Mirror type

$$[\nu^*_L], \qquad l^*_L, \qquad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

3. Homodoublet type

$$\begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_L, \qquad \begin{pmatrix} \nu^* \\ l^* \end{pmatrix}_R.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their minimal gauge couplings. The couplings of excited leptons with Z are given by

$$\frac{e}{2\sin\theta_W \cos\theta_W}(-1 + 2\sin^2\theta_W)\bar{l}^*\gamma^\mu l^* Z_\mu + \frac{e}{2\sin\theta_W \cos\theta_W}\bar{\nu}^*\gamma^\mu \nu^* Z_\mu$$

in the homodoublet model. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^2 \neq 0$, they are usually neglected.

Excited fermions may also be produced via the contact interactions with ordinary quarks and leptons [42]

$$\mathcal{L} = \frac{g^2_{\rm contact}}{\Lambda^2}\left[\eta'_{LL}(\bar{\psi}_L\gamma_\mu\psi_L)(\bar{\psi}^*_L\gamma^\mu\psi^*_L) + (\eta''_{LL}(\bar{\psi}_L\gamma_\mu\psi_L)(\bar{\psi}^*_L\gamma^\mu\psi_L) + \text{h.c.}) + \cdots\right]. \qquad (91.4)$$

Again, the coefficient is conventionally taken $g^2_{\rm contact} = 4\pi$. It is widely assumed $\eta'_{LL} = \eta''_{LL} = 1$, $\eta'_{LR} = \eta''_{LR} = \eta'_{RL} = \eta''_{RL} = \eta'_{RR} = \eta''_{RR} = 0$ in experimental analyses for simplicity.

In addition, transition-magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\begin{aligned}\mathcal{L} =& \frac{\lambda_\gamma^{(\psi^*)} e}{2m_{\psi^*}} \bar{\psi}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \psi F_{\mu\nu} \\ &+ \frac{\lambda_Z^{(\psi^*)} e}{2m_{\psi^*}} \bar{\psi}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) \psi Z_{\mu\nu} \\ &+ \frac{\lambda_W^{(l^*)} g}{2m_{l^*}} \bar{l}^* \sigma^{\mu\nu} \frac{1-\gamma_5}{2} \nu W_{\mu\nu} \\ &+ \frac{\lambda_W^{(\nu^*)} g}{2m_{\nu^*}} \bar{\nu}^* \sigma^{\mu\nu} (\eta_L \frac{1-\gamma_5}{2} + \eta_R \frac{1+\gamma_5}{2}) l W^\dagger_{\mu\nu} \\ &+ \text{h.c.}, \end{aligned} \tag{91.5}$$

where $g = e/\sin\theta_W$, $\psi = \nu$ or l, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the photon field strength, $Z_{\mu\nu} = \partial_\mu Z_\nu - \partial_\nu Z_\mu$, *etc.*. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L \eta_R = 0. \tag{91.6}$$

These couplings in Eq. (91.5) can arise from $SU(2) \times U(1)$-invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type l^* with the Lagrangian (see [43, 44])

$$\mathcal{L} = \frac{1}{2\Lambda} \bar{L}^* \sigma^{\mu\nu} (g f \frac{\tau^a}{2} W^a_{\mu\nu} + g' f' Y B_{\mu\nu}) \frac{1-\gamma_5}{2} L + \text{h.c.}, \tag{91.7}$$

where L denotes the lepton doublet (ν, l), Λ is the compositeness scale, g, g' are $SU(2)$ and $U(1)_Y$ gauge couplings, and $W^a_{\mu\nu}$ and $B_{\mu\nu}$ are the field strengths for $SU(2)$ and $U(1)_Y$ gauge fields. These couplings satisfy the relation

$$\lambda_W = -\sqrt{2} \sin^2\theta_W (\lambda_Z \cot\theta_W + \lambda_\gamma), \tag{91.8}$$

with $\lambda_{W,Z,\gamma}$ being defined in Eq. (91.5) with $\lambda_{W,Z,\gamma} = \lambda^{(\ell^*)}_{W,Z,\gamma}$ or $\lambda_{W,Z,\gamma} = \lambda^{(\nu^*)}_{W,Z,\gamma}$. Here $(\eta_L, \eta_R) = (1, 0)$ is assumed. It should be noted that the electromagnetic radiative decay of l^* (ν^*) is forbidden if $f = -f'$ $(f = f')$.

Additional coupling with gluons is possible for excited quarks:

$$\begin{aligned}\mathcal{L} = \frac{1}{2\Lambda} \bar{Q}^* \sigma^{\mu\nu} \left(g_s f_s \frac{\lambda^a}{2} G^a_{\mu\nu} + g f \frac{\tau^a}{2} W^a_{\mu\nu} + g' f' Y B_{\mu\nu} \right) \\ \times \frac{1-\gamma_5}{2} Q + \text{h.c.}, \end{aligned} \tag{91.9}$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G^a_{\mu\nu}$ the gluon field strength.

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (l_8) and the ordinary lepton (l) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_l \left\{ \bar{l}^\alpha_8 g_S F^\alpha_{\mu\nu} \sigma^{\mu\nu} (\eta_L l_L + \eta_R l_R) + \text{h.c.} \right\} \tag{91.10}$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L \eta_R = 0$ as before.

Searches for the excited quarks and leptons have been performed over the last decades in experiments at the LEP [45–48], HERA [49, 50], Tevatron [51, 52], and LHC [53–78]. Most stringent constraints, which are described below at 95% confidence level, come from the LHC experiments.

The signature of excited quarks q^* at hadron colliders is characterized by a narrow resonant peak in the reconstructed invariant mass distribution of the q^* decay products. The decays via the transition-magnetic type operator in Eq. (91.9) are considered for excited quarks in LHC searches, and the final states to search for are dijet (qg) [53, 54, 66–69] or a jet in association with a photon $(q\gamma)$ [55, 56, 70, 71] or a weak gauge boson (qW, qZ) [72, 73]. All analyses consider only spin-1/2 excited states of first generation quarks (u^*, d^*) with degenerate masses, expected to be predominantly produced in proton-proton collisions except for the excited b quark searches described below. Only the minimal gauge interactions and the transition-magnetic couplings with the form given in Eq. (91.9) are considered in the production process, and hence the contact interactions in Eq. (91.4) are not considered. The compositeness scale Λ is taken to be the same as the excited quark mass m_{q^*}. The transition-magnetic coupling coefficients f_s, f and f' are assumed to be equal to 1 (denoted by f).

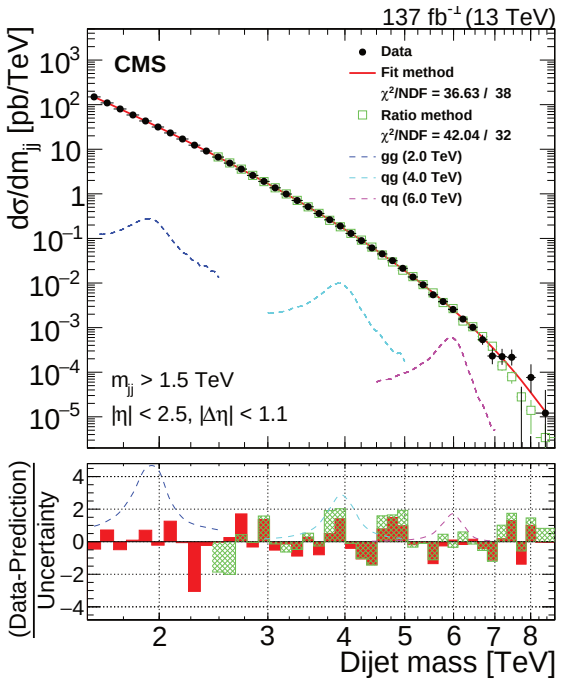

Figure 91.3: Dijet mass distribution measured by CMS using wide jets reconstructed from two highest transverse momentum jets by adding nearby jets within $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$. The data distribution is compared to a fit representing a smooth background spectrum (solid curve) and the background prediction obtained from the $\Delta\eta_{\rm jj}$ control regions (open squares), denoted as Ratio method, at $\rm m_{jj} > 2.4$ TeV. The excited quark signal with mass of 4.0 TeV (labeled as qg) is shown together with other benchmark signals. Shown at the bottom panel is the difference between the data and the fitted parametrization from the fit method or the data and the background prediction from the Ratio method, divided by the statistical uncertainty of the data. Figure adopted from [69].

With proton-proton collision data recorded at $\sqrt{s} = 13$ TeV at the LHC, the excited quark masses are excluded in dijet resonance searches up to 6.7 TeV in ATLAS using 139 fb^{-1} [54] and 6.3 TeV in CMS using 137 fb^{-1} [69]. Figure 91.3 shows the dijet mass ($\rm m_{jj}$) distribution measured in CMS [69] by using the two highest $p_{\rm T}$ jets reconstructed with the anti-$k_{\rm T}$ algorithm [79] of a distance parameter of 0.4, and by combining nearby jets within $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2} < 1.1$ around the leading two jets. The measured dijet mass spectrum is compared to a fit with smoothly falling background shape (solid curve) at $\rm m_{jj} > 1.5$ TeV and the background prediction obtained from the $\Delta\eta_{\rm jj}$ control regions (open squares), denoted as Ratio method, at $\rm m_{jj} > 2.4$ TeV to look for a narrow resonance. Here $\Delta\eta_{\rm jj}$ is the pseudorapidity separation between the two jets. An excited quark signal with mass of 4.0 TeV is shown in the figure (denoted by qg) as one of the

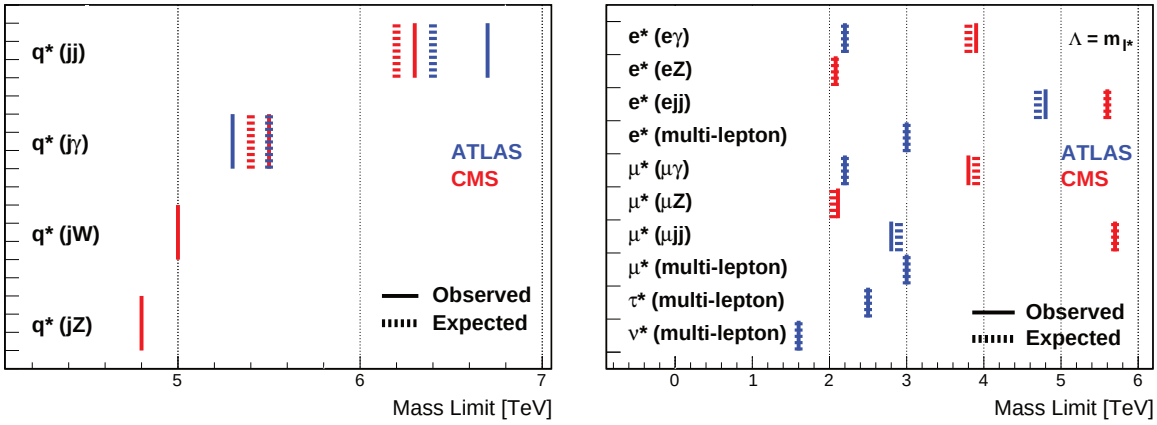

Figure 91.4: 95% C.L. lower mass limits for the excited quarks (left) and excited leptons (right) at ATLAS [54, 56, 62–64] and CMS [69, 71, 73, 76–78] experiments. Shown are the most stringent limits for each final state (denoted in parentheses) of the excited fermions from both experiments. Only first generation quarks (u, d) with transition-magnetic type interactions with $f_s = f = f' = 1$ are considered for the excited quarks. The excited lepton limits are given for the production via contact interactions with $\Lambda = m_{l^*}$.

benchmark signals considered in the analysis.

The photon + jet resonance searches, targeting excited quarks decaying into a quark and a photon ($q^* \to q + \gamma$), have excluded q^* masses up to 5.3 TeV in ATLAS [56] and 5.5 TeV in CMS [71] using collision data at $\sqrt{s} = 13$ TeV. The W/Z boson + jet final states are examined to look for the $q^* \to q + W$ and $q + Z$ signal in CMS [73], exploiting jet substructure technique designed to provide sensitivity for highly-boosted hadronically decaying W and Z bosons. The lower mass limit of 5.0 (4.8) TeV is obtained from the W + jet (Z + jet) search using dataset recorded at $\sqrt{s} = 13$ TeV.

The excited b quarks (b^*) are also considered in the present searches at the LHC. Assuming the similar production processes to the first-generation excited quarks, the b^* has been searched for in final states containing at least one jet identified as originating from a b quark (b-tagging). The searches using two jets including at least one b-tagged jet have been performed at 8 and 13 TeV [54, 57, 58, 67], resulting in b^* lower mass limits of 3.2 TeV in ATLAS using 139 fb^{-1} at $\sqrt{s} = 13$ TeV [54] and 1.6 TeV in CMS using 19.7 fb^{-1} at $\sqrt{s} = 8$ TeV [67]. The CMS Collaboration also performed a search for $b^* \to b + \gamma$ in events with a b-tagged jet in association with a photon using data at $\sqrt{s} = 13$ TeV [71], and excluded b^* masses up to 1.8 TeV. Excited b quarks with charged-current decay into a W-boson and a top quark ($b^* \to t + W$) were looked for in both ATLAS and CMS using the full 8 TeV data [59, 74]. ATLAS excluded b^* masses below 1.5 TeV for the b^* with left- and right-handed couplings [59] while CMS excluded the masses below 1.39(1.43) TeV for the left(right)-handed couplings [74].

The excited top quarks (t^*) have also been searched for at the LHC. The CMS Collaboration performed the search for pair-produced t^* quarks with the assumption of the t^* quark decay into a top quark and a gluon, in events with a charged lepton, missing transverse momentum and multiple jets including b-tagged jets at $\sqrt{s} = 8$ TeV [80] and 13 TeV [81]. With 35.9 fb^{-1} data at 13 TeV, CMS excluded the t^* masses below 1.2 TeV for spin 3/2 t^* quarks [81].

Searches for excited leptons l^* are also performed at the LHC using proton-proton collision data recorded at $\sqrt{s} = 7$ and 8 TeV [61–65, 75, 76] as well as at 13 TeV [77]. Considering single l^* production in contact interactions (Eq. (91.4)) and electromagnetic radiative decay to a SM lepton and a photon ($l^* \to l + \gamma$ where $l = e, \mu$), the excited electron and muon masses are excluded for $\Lambda = m_{l^*}$ up to 3.9 and 3.8 TeV, respectively, using 35.9 fb^{-1} at $\sqrt{s} = 13$ TeV in CMS [77] and 2.2 TeV using 13 fb^{-1} at $\sqrt{s} = 8$ TeV in ATLAS [62].

With the full 20.3 fb^{-1} data at $\sqrt{s} = 8$ TeV, the inclusive search on multi-lepton signatures with 3 or more charged leptons in ATLAS [63] further constrains the excited charged leptons and neutrinos. Considering both the transition-magnetic (Eq. (91.7)) and contact interaction (Eq. (91.4)) processes, the lower mass limits for the e^*, μ^*, τ^* and ν^* (for every excited neutrino flavor) are obtained to be 3.0, 3.0, 2.5 and 1.6 TeV, respectively, for $\Lambda = m_{e^*}$, m_{μ^*}, m_{τ^*} and m_{ν^*}. The rate of pair-produced excited leptons is independent of Λ for the minimal gauge interaction processes, and it allows to improve search sensitivity with multi-lepton signatures at high Λ, especially for excited neutrinos because the predominant $\nu_l^* \to l + W$ decays result in a higher acceptance for ≥ 3 charged lepton final states.

Both ATLAS and CMS Collaborations performed searches for singly produced excited leptons. The single excited leptons, both produced and decayed in contact interaction processes (Eq. (91.4)), were searched for in CMS using 77.4 fb^{-1} at 13 TeV [78] and in ATLAS using 20.3 fb^{-1} at 8 TeV [64] using the final states with two leptons and two jets ($q\bar{q} \to ll^* \to llq\bar{q}$). The CMS search [78] considered both excited electrons and excited muons, using the invariant mass of the combination of the two leptons and two jets as a discriminating variable to separate signal from background. The ATLAS search [64] considered only excited muons. The single excited electrons, produced in contact interactions and decayed either in contact interaction or charged-current processes, were considered in ATLAS using 36.1 fb^{-1} at 13 TeV [65] in the final states with two electrons and two jets ($q\bar{q} \to ee^* \to eeq\bar{q}$) or an electron, missing transverse momentum and a hadronically decaying W-boson candidate ($q\bar{q} \to ee^* \to e\nu W$). The excited electron (muon) mass was excluded up to 5.6 (5.7) TeV in CMS [78] at $\Lambda = m_{e^*}$ ($\Lambda = m_{\mu^*}$), which is the best limit to date on the excited electrons (muons).

The CMS Collaboration also performed an excited lepton search in the final states containing a Z boson [76], probing the excited leptons produced in contact interactions and decayed in neutral-current processes ($l^* \to l + Z$) with $f = f' = 1$ or $f = -f' = 1$. The leptonic and hadronic decays of Z bosons have been considered in the search, and the most stringent limits are obtained from the hadronic Z decay to be 2.08 (2.34) TeV and 2.11 (2.37) TeV for the e^* and μ^*, respectively, with $f = f' = 1$ ($f = -f' = 1$) at $\Lambda = m_{l^*}$.

Figure 91.4 summarizes the most stringent 95% C.L. lower mass limits for excited quarks and leptons obtained from the LHC experiments.

92. Dynamical Electroweak Symmetry Breaking: Implications of the H^0

Revised August 2021 by K.M. Black (Wisconsin U.), R. Sekhar Chivukula (UC San Diego) and M. Narain (Brown U.).

92.1 Introduction and Phenomenology

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a composite operator, typically a fermion bilinear. In these theories, the longitudinal components of the massive weak bosons are identified with composite Nambu-Goldstone bosons arising from dynamical symmetry breaking in a strongly-coupled extension of the standard model. Viable theories of dynamical electroweak symmetry breaking must also explain (or at least accommodate) the presence of an additional composite scalar state to be identified with the H^0 scalar boson [1,2] – a state unlike any other observed previously.

Theories of dynamical electroweak symmetry breaking can be classified by the nature of the composite singlet state to be associated with the H^0 and the corresponding dimensional scales f, the analog of the pion decay-constant in QCD, and Λ, the scale of the underlying strong dynamics.[1] Of particular importance is the ratio v/f, where $v^2 = 1/(\sqrt{2}G_F) \approx (246\,\text{GeV})^2$, since this ratio measures the expected size of the deviations of the couplings of a composite Higgs boson from those expected in the standard model. The basic possibilities, and the additional states that they predict, are described below.

92.1.1 *Technicolor, $v/f \simeq 1$, $\Lambda \simeq 1$ TeV*

Technicolor models [7–9] provided the first examples of theories of dynamical electroweak symmetry breaking. These theories incorporate a new asymptotically free gauge theory ("technicolor") and additional massless fermions ("technifermions" transforming under a vectorial representation of the gauge group). The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral symmetry in QCD is broken down to isospin by the formation of a quark condensate. The $\text{SU}(2)_W \times \text{U}(1)_Y$ interactions are embedded in the global technifermion chiral symmetries in such a way that the only unbroken gauge symmetry after chiral symmetry breaking is $\text{U}(1)_{em}$.[2] The theories naturally provide the Nambu-Goldstone bosons "eaten" by the W and Z boson. There would also typically be additional heavy states (e.g. vector mesons, analogous to the ρ and ω mesons in QCD) with TeV masses [13,14], and the WW and ZZ scattering amplitudes would be expected to be strong at energies of order 1 TeV.

There are various possibilities for the scalar H^0 in technicolor models. First, the H^0 could be identified as a singlet scalar resonance, analogous to the σ particle expected in pion-scattering in QCD [15, 16]. Alternatively, the H^0 could be identified as a dilaton, a (pseudo-)Goldstone boson of scale invariance in theories of "walking technicolor" [17–21].[3] Finally, the H^0 could be identified as an additional isosinglet state if the chiral symmetry breaking pattern of the technicolor theory provides for such a state.[4] In all of these cases, however, one expects large deviations in the couplings of this particle from those of the standard model Higgs boson. Since the couplings observed for the H^0 approximate those of the Higgs boson to the 10% level, models of this kind are very highly constrained.

92.1.2 *The Higgs doublet as a pseudo-Nambu-Goldstone Boson, $v/f < 1$, $\Lambda > 1$ TeV*

In technicolor models, the symmetry-breaking properties of the underlying strong dynamics necessarily breaks the electroweak gauge symmetries. An alternative possibility is that the underlying strong dynamics itself does not break the electroweak interactions, and that the entire quartet of bosons in the Higgs doublet (including the state associated with the H^0) are composite (pseudo-) Nambu-Goldstone particles [23–25]. In this case, the underlying dynamics can occur at energies exceeding 1 TeV and additional interactions with the top-quark mass generating sector (and possibly with additional weakly-coupled gauge bosons) cause the vacuum energy to be minimized when the composite Higgs doublet gains a vacuum expectation value [26, 27]. In these theories, the couplings of the remaining singlet scalar state would naturally be equal to that of the standard model Higgs boson up to corrections of order $(v/f)^2$ and, therefore, constraints on the size of deviations of the H^0 couplings from that of the standard model Higgs [28] give rise to lower bounds on the scales f and Λ.[5]

The electroweak gauge interactions, as well as the interactions responsible for the top-quark mass, explicitly break the chiral symmetries of the composite Higgs model and lead generically to sizable corrections to the mass-squared of the Higgs-doublet – the so-called "Little Hierarchy Problem" [29]. "Little Higgs" theories [30–33] are examples of composite Higgs models in which the (collective) symmetry-breaking structure is selected so as to suppress these contributions to the Higgs mass-squared.

Composite Higgs models typically require a larger global symmetry of the underlying theory, and hence additional relatively light (compared to Λ) scalar particles, extra electroweak vector bosons (e.g. an additional $\text{SU}(2)\times\text{U}(1)$ gauge group), and vector-like partners of the top-quark of charge $+2/3$ and possibly also $+5/3$ [34]. In addition to these states, one would expect the underlying dynamics to yield additional scalar and vector resonances with masses of order Λ. If the theory respects a custodial symmetry [35], the couplings of these additional states to the electroweak and Higgs boson will be related – and, for example, one might expect a charged vector resonance to have similar branching ratios to WZ and WH. Different composite Higgs models utilize different mechanisms for arranging for the hierarchy of scales $v < f$ and arranging for a scalar Higgs self-coupling small enough to produce an H^0 of mass of order 125 GeV, for a review see [36] . If the additional states in these models carry color, they can provide additional contributions to Higgs production via gluon fusion [37]. The extent to which Higgs production at the LHC conforms with standard model predictions provides additional constraints (typically lower bounds on the masses of the additional colored states of order 0.7 TeV) on these models.

In addition, if the larger symmetry of the underlying composite Higgs theory does not commute with the standard model gauge group, then the additional states found in those models – especially those related to the top-quark, which tend to have the largest couplings to the electroweak sector – may be *colorless*. For example, in twin Higgs models [38], the top-partners carry no standard model charges. The phenomenology of the additional states in twin Higgs theories is rather different, since lacking color the production of these particles at the LHC will be suppressed – and, their decays may occur only via the electroweak symmetry breaking sector, leading to their being long-lived.

92.1.3 *Top-Condensate, Top-Color, Top-Seesaw and related theories, $v/f < 1$, $\Lambda > 1$ TeV*

A final alternative is to consider a strongly interacting theory with a high (compared to a TeV) underlying dynamical scale that *would* naturally break the electroweak interactions, but whose

[1] In a strongly interacting theory "Naive Dimensional Analysis" [3, 4] implies that, in the absence of fine-tuning, $\Lambda \simeq g^* f$ where $g^* \simeq 4\pi$ is the typical size of a strong coupling in the low-energy theory [5, 6]. This estimate is modified in the presence of multiple flavors or colors [7] .

[2] For a review of technicolor models, see [10–12].

[3] If both the electroweak symmetry and the approximate scale symmetry are broken only by electroweak doublet condensate(s), then the decay-constants for scale and electroweak symmetry breaking may be approximately equal – differing only by terms formally proportional to the amount of explicit scale-symmetry breaking.

[4] In this case, however, the coupling strength of the singlet state to WW and ZZ pairs would be comparable to the couplings to gluon and photon pairs, and these would all arise from loop-level couplings in the underlying technicolor theory [22].

[5] In these models v/f is an adjustable parameter, and in the limit $v/f \to 1$ they reduce, essentially, to the technicolor models discussed in the previous subsection. Our discussion here is consistent with that given there, since we expect corrections to the SM Higgs couplings to be large for $v/f \simeq 1$. Current measurements constrain the couplings of the H^0 to equal those predicted for the Higgs in the standard model to about the 10% level [28], suggesting that f must have values of order a TeV or higher and, therefore, a dynamical scale Λ of at least several TeV.

strength is adjusted ("fine-tuned") to produce electroweak symmetry breaking at 1 TeV. This alternative is possible if the electroweak (quantum) phase transition is continuous (second order) in the strength of the strong dynamics [39]. If the fine-tuning can be achieved, the underlying strong interactions will produce a light composite Higgs bound state with couplings equal to that of the standard model Higgs boson up to corrections of order $(1\ \mathrm{TeV}/\Lambda)^2$. As in theories in which electroweak symmetry breaking occurs through vacuum alignment, therefore, constraints on the size of deviations of the H^0 couplings from that of the standard model Higgs give rise to lower bounds on the scale Λ. Formally, in the limit $\Lambda \to \infty$ (a limit which requires arbitrarily fine adjustment of the strength of the high-energy interactions), these theories are equivalent to a theory with a fundamental Higgs boson – and the fine adjustment of the coupling strength is a manifestation of the hierarchy problem of theories with a fundamental scalar particle.

In many of these theories the top-quark itself interacts strongly (at high energies), potentially through an extended color gauge sector [40, 40–44]. In these theories, top-quark condensation (or the condensation of an admixture of the top with additional vector-like quarks) is responsible for electroweak symmetry breaking, and the H^0 is identified with a bound state involving the third generation of quarks. These theories typically include an extra set of massive color-octet vector bosons (top-gluons), and an extra $U(1)$ interaction (giving rise to a top-color Z') which couple preferentially to the third generation and whose masses define the scale Λ of the underlying physics.

92.1.4 *Flavor*

In addition to the electroweak symmetry breaking dynamics described above, which gives rise to the masses of the W and Z particles, additional interactions must be introduced to produce the masses of the standard model fermions. Two general avenues have been suggested for these new interactions. In "extended technicolor" (ETC) theories [45, 46], the gauge interactions in the underlying strongly interacting theory are extended to incorporate flavor. This extended gauge symmetry is broken down (possibly sequentially, at several different mass scales) to the residual strong interaction responsible for electroweak symmetry breaking. The massive gauge-bosons corresponding to the broken symmetries then mediate interactions between mass operators for the quarks/leptons and the corresponding bilinears of the strongly-interacting fermions, giving rise to the masses of the ordinary fermions after electroweak symmetry breaking.

In the case of "partial compositeness" [47], the additional flavor-dependent interactions arise from mixing between the ordinary quarks and leptons and massive composite fermions in the strongly-interacting underlying theory. Theories incorporating partial compositeness include additional vector-like partners of the ordinary quarks and leptons, typically with masses of order a TeV or less.

In both cases, the effects of flavor interactions on the electroweak properties of the ordinary quarks and leptons are likely to be most pronounced in the third generation of fermions.[6] The additional particles present in these theories, especially the additional scalars, often couple more strongly to heavier fermions.

Moreover, since the flavor interactions must give rise to quark mixing, we expect that a generic theory of this kind could give rise to large flavor-changing neutral-currents [46]. In ETC theories, these constraints are typically somewhat relaxed if the theory incorporates approximate generational flavor symmetries [48], the theory has a slowly running coupling constant or "walks" [17–21], or if $\Lambda > 1$ TeV [49]. In theories of partial compositeness, the masses of the ordinary fermions depend on the scaling-dimension of the operators corresponding to the composite fermions with which they mix. This leads to a new mechanism for generating the mass-hierarchy of the observed quarks and leptons that, potentially, ameliorates flavor-changing neutral current problems and can provide new contributions to the composite Higgs potential which allow for $v/f < 1$ [50–54].

Alternatively, one can assume that the underlying flavor dynamics respect flavor symmetries ("minimal" [55, 56] or "next-to-minimal" [57] flavor violation) that suppress flavor-changing neutral currents in the two light generations. Additional considerations apply when extending these arguments to potential explanation of neutrino masses (see, for example, [58, 59]).

92.1.5 *Theoretical Considerations*

Since the underlying high-energy dynamics in these theories are strongly coupled, there are no reliable calculation techniques that can be applied to analyze their properties. Instead, most phenomenological studies depend on the construction of a "low-energy" effective theory describing additional scalar, fermion, or vector boson degrees of freedom, which incorporates the relevant symmetries and, when available, dynamical principles. In some cases, motivated by the AdS/CFT correspondence [60], the strongly-interacting theories described above have been investigated by analyzing a dual compactified five-dimensional gauge theory. In these cases, the AdS/CFT "dictionary" is used to map the features of the underlying strongly coupled high-energy dynamics onto the low-energy weakly coupled dual theory [61].

More recently, progress has been made in investigating strongly-coupled models using lattice gauge theory [62–65]. These calculations offer the prospect of establishing which strongly coupled theories of electroweak symmetry breaking have a particle with properties consistent with those observed for the H^0 – and for establishing concrete predictions for these theories at the LHC [66].

92.1.6 *Summary*

The theoretical ideas and models reviewed here motivate searches for a wide variety of new states. Heavy vector bound states decaying to dibosons and additional scalar states appear naturally in both technicolor (92.1.1) and composite higgs models (92.1.2). Composite Higgs models based on collective symmetry breaking naturally include W', Z', and vector-like quark states (especially for the third-generation, and potentially including charge +5/3 custodial top-partner quarks). Vector-like states are also natural for any theory including partial compositeness in order to address the flavor problem (92.1.4). Top-condensate and related models (92.1.3) predict the existence of colorons which preferentially couple to third-generation quarks. Finally, the new states discussed here also occur in extra-dimensional models [61], which is understandable given that many strongly-coupled theories can be viewed as compactified five-dimensional gauge theories via duality (92.1.5). We turn now to a review the status of experimental searches related to dynamical electroweak symmetry breaking.

92.2 Experimental Searches

As discussed above, the extent to which the couplings of the H^0 conform to the expectations for a standard model Higgs boson constrains the viability of each of these models. Measurements of the H^0 couplings, and their interpretation in terms of effective field theory, are summarized in the H^0 review in this volume. In what follows, we will focus on searches for the additional particles that might be expected to accompany the singlet scalar: extra scalars, fermions, and vector bosons. In some cases, detailed model-specific searches have been made for the particles described above (though generally not yet taking account of the demonstrated existence of the H^0 boson).

In most cases, however, generic searches (e.g. for extra W' or Z' particles, extra scalars in the context of multi-Higgs models, or for fourth-generation quarks) are quoted that can be used – when appropriately translated – to derive bounds on a specific model of interest.

The mass scale of the new particles implied by the interpretations of the low mass of H^0 discussed above, and existing studies from the Tevatron and lower-energy colliders, suggests that only the Large Hadron Collider has any real sensitivity. A number of analyses already carried out by ATLAS and CMS use relevant final states and might have been expected to observe a deviation from standard model expectations – in no case so far has any such deviation been reported. The detailed implications of these

[6] Indeed, from this point of view, the vector-like partners of the top-quark in top-seesaw and little Higgs models can be viewed as incorporating partial compositeness to explain the origin of the top quark's large mass.

searches in various model frameworks are described below.

Except where otherwise noted, all limits in this section are quoted at a confidence level of 95%. The searches at $\sqrt{s} = 8$ TeV (Run 1) are based on 20.3 fb^{-1} of data recorded by ATLAS, and an integrated luminosity of 19.7 fb^{-1} analyzed by CMS. The datasets collected at $\sqrt{s} = 13$ TeV during Run 2 of the LHC since 2015 are based on analyses with varied integrated luminosities ranging from ∼2-140 fb^{-1}.

92.2.1 *Searches for Z′ or W′ Bosons*

Massive vector bosons or particles with similar decay channels would be expected to arise in Little Higgs theories, in theories of Technicolor, or models involving a dilaton, adjusted to produce a light Higgs boson, consistent with the observed H^0. These particles would be expected to decay to pairs of vector bosons, or to third generation quarks, or to leptons. The generic searches for W' and Z' vector bosons listed below can, therefore, be used to constrain models incorporating a composite Higgs-like boson.

A general review of searches for Z' and W' bosons is also included in this volume [67, 68]. In the context of the dynamical electroweak symmetry breaking models, we emphasize their decays to third generation fermions by including a detailed overview, while also briefly summarizing the other searches.

$Z' \to \ell\ell$:

ATLAS [69] and CMS [70] have both searched for Z' production with $Z' \to ee$ or $\mu\mu$. No deviation from the standard model prediction was seen in the dielectron and dimuon invariant mass spectra, by either the ATLAS or the CMS analysis, and lower limits on possible Z' boson masses were set. A $Z'_{\rm SSM}$ with couplings equal to the standard model Z' (a "sequential standard model" Z') and a mass below 5.1 TeV was excluded by ATLAS, while CMS set a lower mass limit of 5.15 TeV. The experiments also place limits on the parameters of extra dimension models and in the case of ATLAS on the parameters of a minimal walking technicolor model [17–21], consistent with a 125 GeV Higgs boson [71]. For a general review of searches in these channels see the PDG review of Z prime in this volume [67].

In addition, both experiments have also searched for Z' decaying to a ditau final state [72, 73]. An excess in $\tau^+\tau^-$ could have interesting implications for models in which lepton universality is not a requirement and enhanced couplings to the third generation are allowed. This analysis led to lower limits on the mass of a $Z'_{\rm SSM}$ of 2.4 and 2.1 TeV from ATLAS and CMS respectively.

$Z' \to q\bar{q}$:

The ability to relatively cleanly select $t\bar{t}$ pairs at the LHC together with the existence of enhanced couplings to the third generation in many models makes it worthwhile to search for new particles decaying in this channel. Both ATLAS [74] and CMS [75] have carried out searches for new particles decaying into $t\bar{t}$.

Both the ATLAS and CMS collaborations searched for $t\bar{t}$ in the all hadronic mode [76] [77] in both the resolved and boosted regions. No evidence of resonance production were seen and limits were produced for various models including the Z' boson in topcolor-assisted technicolor which excludes masses less than 3.1 to 3.6 TeV (ATLAS) depending on the details of the model and 3.3, 5.25, and 6.65 TeV for widths of 1, 10 and 30 percent relative to the mass of the resonance .

ATLAS also presented results on the lepton plus jets final state, where the top quark pair decays as $t\bar{t} \to WbWb$ with one W boson decaying leptonically and the other hadronically; CMS used final states where both, one or neither W decays leptonically and then combined the results. The $t\bar{t}$ invariant mass spectrum was analyzed for any excess, and no evidence for any resonance was seen. ATLAS excluded a narrow ($\Gamma/m = 1.2\%$) leptophobic topcolor Z' boson with masses between 0.7 and 2.1 TeV and with $\Gamma/m = 3\%$ between 0.7 and 3.2 TeV. CMS set limits on leptophobic Z' bosons for three different assumed widths $\Gamma/m = 1.0\%$, $\Gamma/m = 10.0\%$, and $\Gamma/m = 30.0\%$ of 3.9 TeV to 4.0 TeV and exclude RS KK gluons up to 3.3 TeV.

Both ATLAS [78] and CMS [79] have also searched for resonances decaying into $q\bar{q}$, qg or gg using the dijet invariant mass spectrum. Excited quarks are excluded up to masses of 6.7 TeV and model-independent upper limits on cross sections with a Gaussian signal shape were set. CMS excluded string resonances with masses below 7.9 TeV, scalar diquarks below 7.5 TeV, axigluons and colorons below 6.6 TeV, excited quarks below 6.3 TeV, color-octet scalars below 3.7 TeV, W' bosons below 3.6 TeV, Z' bosons with SM-like couplings below 2.9 TeV and between 3.1 TeV and 3.3 TeV, Randall–Sundrum Gravitons below 2.6 TeV.

$W' \to \ell\nu$:

Both LHC experiments have also searched for massive charged vector bosons. In this section we include a summary of the results, with emphasis on final states with third generation fermions, while the details on other decays are discussed in the mini-review of W' [68]. ATLAS searched for a heavy W' decaying to $e\nu$ or $\mu\nu$ and found no excess over the standard model expectation. A sequential standard model (SSM) W' boson (assuming zero branching ratio to WZ) with mass less than 7 TeV was excluded [80] using the 139 fb^{-1} dataset at $\sqrt{s} = 13$ TeV. Model independent cross-section limits as a function of mass were also set. Based on a smaller dataset, the CMS experiment excluded a SSM W' boson with mass up to 4.1 TeV [81] and presented upper limits on the production of generic W' bosons decaying into this final state using a model-independent approach.

CMS [82] has carried out a complementary search in the $\tau\nu$ final state. As noted above, such searches place limits on models with enhanced couplings to the third generation. No excess was observed and limits between 2.0 and 2.7 TeV were set on the mass of a W' decaying preferentially to the third generation; a W' with universal fermion couplings was also excluded for masses less than 2.7 TeV.

$W' \to t\bar{b}$:

Heavy new gauge bosons can couple to left-handed fermions like the SM W boson or to right-handed fermions. W' bosons that couple only to right-handed fermions (W'_R) may not have leptonic decay modes, depending on the mass of the right-handed neutrino. For these W' bosons, the tb ($t\bar{b} + \bar{t}b$) decay mode is especially important because in many models the W' boson is expected to have enhanced couplings to the third generation of quarks relative to those in the first and second generations. It is also the hadronic decay mode with the best signal-to-background. ATLAS and CMS have performed searches for W' bosons via the $W' \to tb$ decay channel in the lepton+jets and all-hadronic final state.

The CMS lepton+jets search [83–86], $W' \to tb \to Wbb \to \ell\nu bb$, proceeded via selecting events with an isolated lepton (electron or muon), and at least two jets, one of which is identified to originate from a b-quark. The mass of the W' boson (M_{tb}) was reconstructed using the four-momentum vectors of the final state objects ($bb\ell\nu$). The distribution of M_{tb} is used as the search discriminant. A search [86] using 35.9 fb^{-1} of data, collected at $\sqrt{s}$ = 13 TeV, led to an exclusion of W'_R bosons with masses below 3.4 TeV (3.6 TeV) if $M_{W'_R} >> M_{\nu_R}$ ($M_{W'_R} < M_{\nu_R}$), where M_{ν_R} is the mass of the right-handed neutrino.

The CMS search for $W' \to tb$ decays using the all-hadronic final state focused on W' masses above 1 TeV [85, 87]. In this region, the top quark gets a large Lorentz boost and hence the three hadronic products from its decay merge into a single large-radius jet. Deep neural network(DNN) algorithms are used to identify the jet initiated by the bottom quark. Techniques including DNN, which rely on substructure information of the jets [88] are employed to identify boosted all hadronic W boson and top quark [87] decays. The W' candidate mass was computed from back-to-back boosted top-tagged jet and a low mass b-tagged jet. From this all-hadronic search, W' bosons were excluded for masses up to 3.4 TeV [87].

ATLAS has searched for W'_R bosons in the $t\bar{b}$ final state both for lepton+jets [89] and all-hadronic [90] decays of the top. No significant deviations from the standard model were seen in either analysis and limits were set on the $W' \to t\bar{b}$ cross section times branching ratio and W' bosons with purely right-handed couplings to fermions were excluded for masses below 3.15 TeV when the two channels are combined.

In addition, the above studies also provided upper limits on the W' effective couplings to right- and left-handed fermions.

In Fig. 92.1 (bottom) the upper limits on W' couplings normalized to the SM W boson couplings derived by ATLAS [91] are shown. The top panel of Fig. 92.1 shows the upper limits for arbitrary combinations of left- and right-handed couplings of the W' boson to fermions set using a model independent approach by CMS [86].

92.2.2 *Searches for Resonances decaying to Vector Bosons and/or Higgs Bosons*

Both the ATLAS and CMS experiments have used the data collected at $\sqrt{s} = 13$ TeV to search for resonances decaying to pairs of bosons. Overall no significant excesses were seen in the full datasets that were analyzed and the results are interpreted in models with heavy vector triplets (HVT) [92], models with strong gravity and extra spatial dimensions, and model independent limits as a function of mass are set. For a full review of models including extra spatial dimensions and the interpretation of many of these results in that context please see the review of extra dimensions in this volume [61].

Utilizing data collected at $\sqrt{s} = 13$ TeV, ATLAS [93] and CMS [94], have both looked for a resonant state decaying into VV (with $V = W$ or Z) , VH (with H representing the SM Higgs boson), and HH. ATLAS searches in the $qqqq$, $\nu\nu qq$, $l\nu qq$, $llqq$, $l\nu l\nu$, $ll\nu\nu$, $l\nu ll$, $llll$, $qqbb$ $\nu\nu bb$, $l\nu bb$, and $llbb$ final states and combined the results . While CMS analyzed the $qqqq$, $\nu\nu qq$, $l\nu qq$, $llqq$, $ll\nu\nu$, $\nu\nu bb$, $l\nu bb$, $llbb$, $bbbb$, $\tau\tau bb$, and $qq\tau\tau$ final states.

The combined limits are expressed both as limits on the cross-section as a function resonance mass as well as constraints on the coupling of the heavy boson triplet to quarks, leptons, and the Higgs boson.

$X \to WZ$:

ATLAS searches for new heavy resonances decaying into WZ in the channels $WZ \to qqqq$ [95] , $l\nu qq$ [96], and $l\nu ll$ [97]. In the fully leptonic channel , the invariant mass of the W Z pair is obtained by considering all possible four lepton permutations in each event. The dominant background is Standard Model continuum WZ production, ZZ production where one lepton is not identified or falls outside the detector acceptance, and top quark plus vector boson production. No resonant production is seen in data and lower limits on the mass of a HVT decaying into WZ are set at 2260 (2460) GeV assuming a coupling constant of $g_V = 1$ ($g_V = 3$). In the $WZ \to l\nu qq$ mode, ATLAS searches in both the cases that the quarks are observed as individual jets (resolved) and where they merge into one jet in the detector (boosted) which probe the low and high p_T regime of the Z boson. No significant excess is seen in either channel and combined lower mass limits are placed at 2900 (3000) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model. In the all hadronic decay mode, ATLAS searches for two high p_T hadronically decaying vector bosons looking for a resonant structure. No excess is seen and limits are placed exclude 1200-3000 (1200-3300) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model.

CMS searches for new heavy resonances in the ZV final state using the semi-leptonic decay channels excluding W' masses up to 1800 GEV in HVT two models with $g_V = 1$ and 3 and in the ZZ channel excludes gravitons up to 1200 GeV. The CMS collaboration searches for $VV \to qqqq$ [98] in the large R dijet search. The W and Z boson are identified through the mass of the large R jet and substructure variables. No excess is seen and limits are set for charged HVT bosons with masses lower than 3200 (3800) GeV for $g_V = 1$ ($g_V = 3$). Cross-section limits as function of mass are reported for the charged spin-1 resonance interpretation and are placed at 44.4 fb at 1.4 TeV to 0.7 pb at 4 TeV. In the $\nu\nu qq$ final state [99], the CMS collaboration searches for a charged spin 1 resonance decaying into a VZ final state with a Z boson decaying into a pair of neutrinos and the other boson decaying into two collimated quarks reconstructed as a large R-jet. The transverse mass of the VZ candidate is reconstructed and utilized to search for evidence of resonant VZ production. No excess is seen and lower mass limits are placed on the charged resonance at 3100 (3400) GeV for $g_V = 1$ ($g_V = 3$) . In the $2l2q$ final state, the CMS collaboration searches for a heavy resonance decaying into ZV [100] looking for events with one large R-jet consistent with the hadronic decay of a vector boson and a Z boson reconstructed in the charged lepton decay channel (e or μ). Limits are set for a HVT W' with a lower mass of 2270 (2330) for $g_V = 1$ ($g_V = 3$) .

$X \to WW$:

The ATLAS collaboration searches for a new heavy resonance decaying into WW in the channels $WW \to qqqq$ [95] , $l\nu qq$ [96], and $l\nu\nu$ [101]. In the case where both Ws decay leptonically, ATLAS utilizes the transverse mass of the two lepton and two neutrino final state and searches for an excess in this distribution between 200 GeV and 5 TeV. No excess is seen and a HVT is excluded for masses below 1300 GeV. Vector boson fusion is also considered and cross-section limits as a function of mass are placed ranging from 1.3 pb to 0.006 pb at 200 GeV to 3 TeV, respectively. In the $l\nu qq$ mode , ATLAS completed a companion analysis to the $WZ \to$ analysis discussed above and places lower mass limits of 2850 (3150) GeV for $g_V = 1$ ($g_V = 3$) in the HVT model. ATLAS also interprets the all hadronic mode analysis in the hypothesis that $WW \to qqqq$ and places limits on a HVT boson decaying into WW in the all hadronic mode between 1200 and 2200 (1200 and 2800) GeV for $g_V = 1$ ($g_V = 3$).

The CMS collaboration searches for $VV \to qqqq$ [98] in the large R dijet search. The W and Z boson are identified through the mass of the large R jet and substructure variables. No excess is seen and limits are set for charged HVT bosons with masses lower than 2700 (2800) GeV for $g_V = 1$ ($g_V = 3$). Cross-section limits as function of mass are reported for the uncharged spin-1 resonance interpretation and are placed at 41.6 fb at 1.4 TeV to 0.6 pb at 4 TeV.

$X \to VH$:

The ATLAS Collaboration searches for a new heavy resonance decaying into WH and ZH in the $qqbb$ (WH and ZH) [102], $l\nu bb$ (WH), $\nu\nu bb$ (ZH), $llbb$(ZH) [103] modes. In the all hadronic mode, ATLAS searches for boosted VH production looking for two large R jets where the larger invariant mass large R jet is interpreted as the Higgs boson decay products while the lesser invariant mass jet is taken to be the hadronically decaying vector boson requiring b-tagging on the Higgs boson subjets. The invariant mass is reconstructed and a search is done for resonant production of ZH. None is found and limits from 1100 to 2500 (1300 to 3800 GeV) are placed for $g_V = 1$ ($g_V = 3$). ATLAS also searches for XH where the W or Z boson decays into $\nu\nu$, $l\nu$, and ll . The analysis searches for both resolved and merged (boosted) b-jets from the decay of the Higgs boson and defines the signal regions based on the number of reconstructed charged leptons (0,1,or 2). In the dilepton channel the invariant mass is explicitly reconstructed of the entire diboson system, the single lepton channel reconstructs the diboson final state constraining the lepton and missing transverse momentum utilizing the known W boson mass, while the 0 charged lepton channel reconstructs the transverse mass of the diboson system. No excess is seen in any channel and limits on the production of a HVT are placed at 2800 GeV (2930) GeV for $g_V = 1$ ($g_V = 3$).

The CMS Collaboration searches for a heavy resonance decaying into VH [104] searching for a resonances decaying into a Higgs boson and a hadronically decaying W or Z boson. The search identifies events with two large-R jets using substructure variables and requires one large-R jets is tagged with a pair of b-hadrons clustered in a single jet. The invariant mass of the VH bosons is reconstructed and evidence for resonance production is sought. No excess is seen and limits are placed. With $g_V = 1$ (3) a narrow W' resonance with $m_{W'} < 2470(3150)$ GeV and $m_{Z'} < 1150(1190)$.

The CMS collaboration searches for a heavy resonance decaying into a pair of boosted Higgs boson with $HH \to b\bar{b}WW^*$ in the single and dilepton channel [105]. Events are categorized according to lepton flavor and multiplicity, along with discriminators that characterize the compatibility with having jets arising from the decay of boosted Higgs and W bosons. The reconstructed Higgs and diHiggs mass distributions are fit and used as the final discriminators. No significant deviations in the 12 sub-categories are seen and 95% confidence limits on spin-0 bosons are set from 24.5 fb at 0.8 TeV to 0.78 fb at 4.5 TeV and spin-2 bosons from

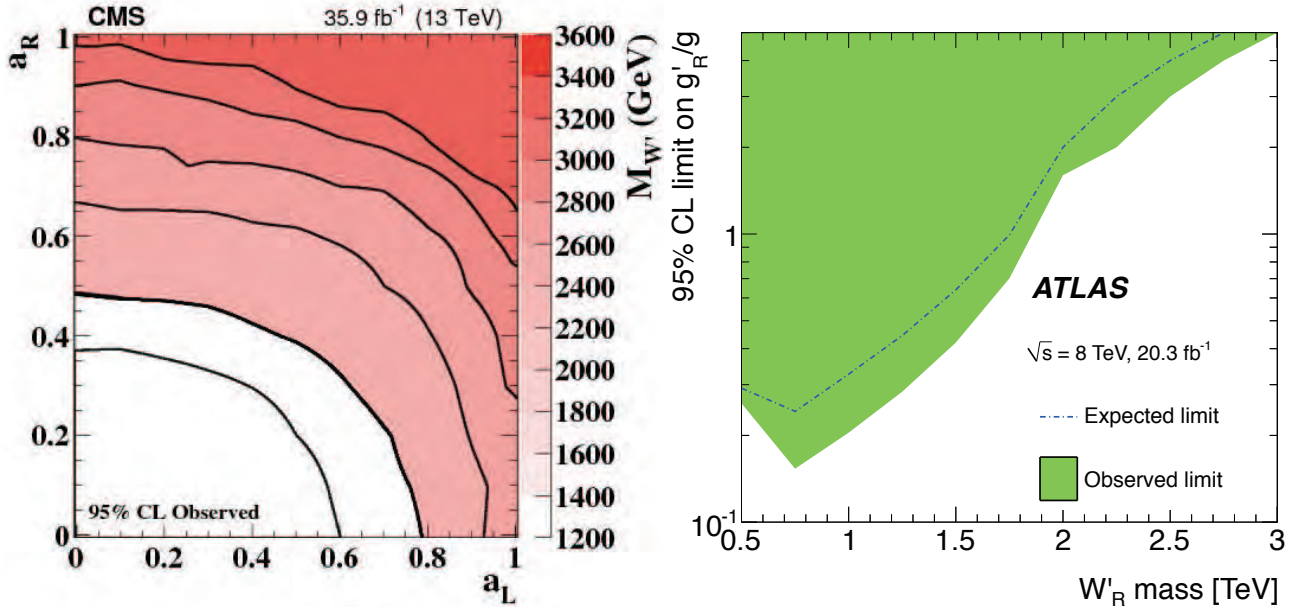

Figure 92.1: Left panel: Observed limits on the W' boson mass as function of the left-handed ($a_{\rm L}$) and right-handed ($a_{\rm R}$) couplings. Black lines represent contours of equal W' boson mass [86]. Right panel: Observed and expected regions, on the g′/g vs mass of the W' boson plane, that are excluded at 95% CL, for right-handed W' bosons [91] showing the exclusion of the values of a hypothetical right-handed coupling of a heavy W particle.

16.7 fb at 0.8 TeV to 0.67 fb at 4.5 TeV. A similar search in the four b-quark final state is used to set limits range 9.74 to 0.29 fb and 4.94 to 0.19 fb in the spin-0 bosons and spin-2 gravitons (respectively) interpretation with masses of 1-3 TeV [106].

$X \to H\gamma$ or $V\gamma$:

Both the CMS and ATLAS collaboration search for heavy resonances decaying into either a vector boson and a photon or a Higgs boson or a photon. These searches are motivated generically by the fact that new heavy gauge bosons are generically predicted to decay to either a Higgs boson or a vector boson and a photon by one loop decays [107]. ATLAS searches for for a heavy resonances decaying into a Higgs boson and a photon and sets limits from 0.7 to 4 TeV from 11.6 fb to 0.11 fb [108]. ATLAS searches for a heavy resonance decaying into XH where $XH \to qqbb$ [109] and sets limits from 1 to 4 TeV. CMS searches for a heavy resonance decaying into a W boson and a photon [110] setting limits for narrow resonances range between 0.17 fb at 6.0 TeV and 55 fb at 0.7 TeV.

Summary of Searches with Diboson Final States:

Both ATLAS [93] and CMS [94] provide plots summarizing the various searches results and limits combining. The results are shown in the context of HVT models and models of strong gravity with extra spatial dimensions. No excess is seen in any search and limits on the 4.3 (4.5) TeV (ATLAS) and (CMS). Inclusion of decays directly to fermions increase these limits to 5.3 (5.5) TeV and 5.0 (5.2) TeV from the ATLAS and CMS combinations, respectively. Both collaborations also place varying limits on the coupling strength as a function of HVT boson mass as well.

Searches for Triboson Resonances:

The CMS collaboration presents the first search for massive triboson resonances in both the semi-leptonic [111] and fully hadronic final state [112]. Three boson final states can be produced via the decay of Kaluza-Klein(KK) states decaying via $W_{KK} \to WR$ with $R \to WW$ where R is a scalar radion. The search utilizes novel deep neural networks to perform optimal separation between signal and background and searches for evidence of resonance structure in the triboson invariant mass-spectrum. No excesses above SM backgrounds are seen and W_{KK} and radion masses are excluded up to $M_{W_{KK}} = 3.4$ TeV and $M_R = 1$ TeV and up to $M_{W_{KK}} = 3.6$ TeV and $M_R = 0.35$ TeV . $M_{W_{KK}}$ below 3 TeV are excluded for $0.6 < \frac{M_R}{M_{W_{KK}}} < 0.7$ in the semi-leptonic final state and up to $M_{W_{KK}} = 3.0$ TeV and $M_R = 200$ GeV and up to $M_{W_{KK}} = 1.5$ TeV and $M_R = 1.5$ TeV in the fully hadronic final state.

92.2.3 *Vector-like third generation quarks*

Vector-like quarks (VLQ) have non-chiral couplings to W bosons, i.e. their left- and right-handed components couple in the same way. They therefore have vectorial couplings to W bosons. Vector-like quarks arise in Little Higgs theories, top-coloron-models, and theories of a composite Higgs boson with partial compositeness. In the following, the notation T quark refers to a vector-like quark with charge 2/3 and the notation B quark refers to a vector-like quark with charge $-1/3$, the same charges as the SM top and b quarks respectively. The exotic vector-like quarks $X_{5/3}$ and $Y_{-4/3}$ have charges 5/3, and $-4/3$ respectively. Vector-like quarks couple with SM quarks with Yukawa interactions and may exist as SU(2) singlets (T, and B), doublets $[(X_{5/3},T),(T,B),(B,Y_{-4/3})]$, or triplets $[(X_{5/3},T,B),(T,B,Y_{-4/3})]$. At the LHC, VLQs can be pair produced via the dominant gluon-gluon fusion process. VLQs can also be produced singly by their electroweak effective couplings to a weak boson and a standard model quark. The single production rate is expected to dominate over the rate of pair production at large VLQ masses. T quarks can decay to bW, tZ, or tH^0. Weak isospin singlets are expected to decay to all three final states with (asymptotic) branching fractions of 50%, 25%, 25%, respectively. Weak isospin doublets are expected to decay exclusively to tZ and to tH^0 [113] with equal branching ratios. Analogously, B quarks can decay to tW, bZ, or bH^0. The $Y_{-4/3}$ and $X_{5/3}$ quarks decay exclusively to bW and to tW. While these are taken as the benchmark scenarios, other representations and decays to exotic new particles are possible [114–116], and hence the final results are interpreted for many allowed branching fraction combinations.

Given the multiple decay modes of the VLQs, the final state signatures of both pair produced and the singly produced VLQs are fairly rich with leptons, jets, b-jets, and missing energy. Depending on the mass of the VLQ, the top quarks and $W/Z/H^0$ bosons may be Lorentz boosted and identified using jet substructure techniques. Thus the searches are performed using lepton+jets signatures, multi-lepton and all-hadronic decays. In addition, T or B quarks with their antiparticles can result in events with same-sign leptons, for example if the decay $T \to tH \to bWW^+W^-$ is present, followed by leptonic decays of two same-sign W bosons.

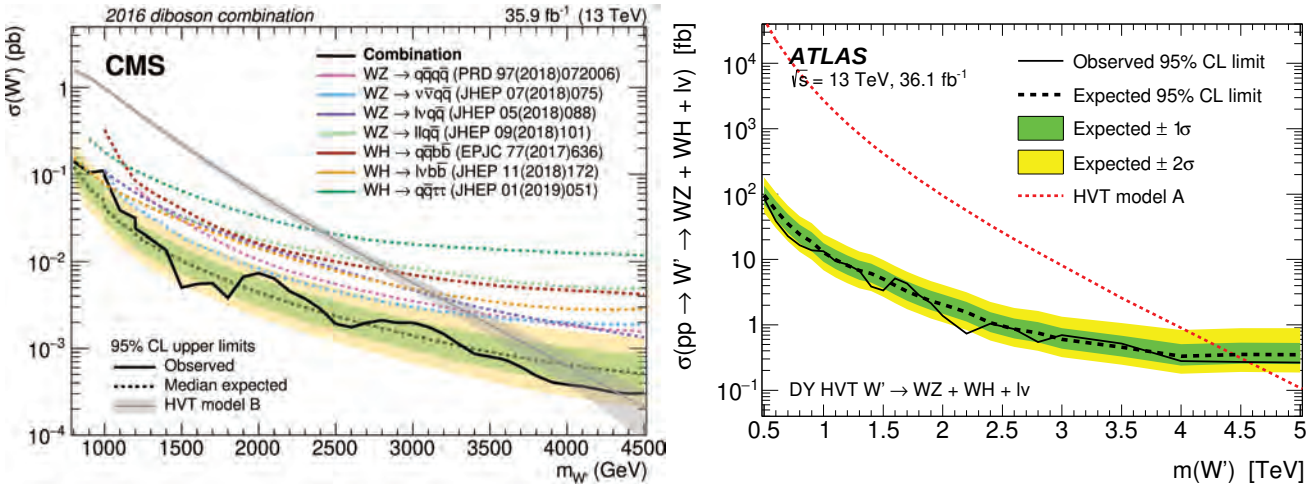

Figure 92.2: Left panel:Observed limits from W' to diboson from CMS [94]. Right panel: Observed limits from W' to diboson decays from ATLAS [93].

In the following subsections, while we describe the searches for each of the decay modes of the VLQs, the same analysis can be re-interpreted to obtain the sensitivity to a combination with varied branching fractions to the different decay modes.

In the following sections, the results obtained for T (B) quarks assuming 100% branching ratio to Wb (Wt) are also applicable to heavy vector-like $Y_{-4/3}$ ($X_{5/3}$) with charge 4/3 (5/3).

92.2.3.1 *Searches for* $\boldsymbol{T}$ *quarks that decay to* $\boldsymbol{W}$, $\boldsymbol{Z}$ *and* $\boldsymbol{H^0}$ *bosons*

$T/Y \to bW$:

CMS has searched for pair production of heavy T quarks that decay exclusively to bW [117–119]. The analysis selected events with exactly one charged lepton, assuming that the W boson from the second T quark decays hadronically. Under this hypothesis, a 2-constraint kinematic fit can be performed to reconstruct the mass of the T quark as a narrow mass peak with a mass resolution of around 7%. In Refs. [118] and [119], the two-dimensional distribution of reconstructed mass vs S_T was used to test for the signal, where S_T is the scalar sum of the missing p_T and the transverse momenta of the lepton and the leading four jets. This analysis, when combined with the search in the fully hadronic final state [120] excluded new quarks that decay 100% to bW for masses below 0.89 TeV [119]. At times the hadronically-decaying W boson is produced with a large Lorentz boost, leading to the W decay products merged into a large-radius jet. Algorithms such as jet pruning [121] were used to remove contributions from soft, wide angle radiation, from large-radius jets, leading to better discrimination between QCD jets and those arising from decays of the heavy particles. If the mass of the boosted jet was compatible with the W boson mass, then the W boson candidate jet and its subjets were used in the kinematic reconstruction of the T quark. No excess over standard model backgrounds was observed. Upper limits on the production cross section as a function of the mass of T quarks were measured. By comparing them with the predicted cross section for vector like quark pair production, the strong pair production of T quarks was excluded for masses below 1.30 TeV (1.28 TeV expected) [117].

Another "cut-based" search for pair produced T quarks in the all-hadronic final state targeting the Wb decay mode [122], relies on mass reconstruction of two highest p_T Wb combinations using boosted W boson candidates with $p_T > 200$ GeV and b-tagged jets. H_T is used as the signal discriminator, with selected events divided into nine categories based on the multiplicity of W and b-jets in the event. From this search T quarks with pure Wb decays are excluded for masses below 1.04 TeV (1.07 TeV expected).

An analogous search has been carried out by ATLAS [123,124] for the pair production of heavy T quarks. It used the lepton+jets final state with an isolated electron or muon and at least four jets, including a b-jet, and required reconstruction of the T quark mass. Given that the mass range for the T quark being explored was from a 0.4 TeV to a couple of TeV, the W boson from the T quark may fall in two categories: those with a high boost leading to merged decay products, and others where the two jets from the W boson were resolved. In addition, the selection was optimized to require large angular separation between the high p_T W bosons and the b-jets.

The $T \to Wb$ candidates were constructed from both the leptonically and hadronically decaying W bosons by pairing them with the two highest p_T b-tagged jets in the event. The pairing of b-jets with W bosons which minimizes the difference between the masses of leptonically decaying T ($m_{lep}(T)$) and the hadronic T ($m_{had}(T)$) was chosen. Finally, $m_{lep}(T)$ was used as the discriminating variable in a signal region defined by high S'_T (here S'_T is defined as the scalar sum of the missing p_T, the p_T of the lepton and jets), and the opening angle between the lepton and the neutrino ($\Delta R(e,\nu)$). With the 36.1 fb^{-1} data collected during Run 2 at $\sqrt{s} = 13$ TeV, assuming 100% branching ratio to the Wb decay, the observed lower limit on the T mass was 1.35 TeV, and in the SU(2) singlet scenario, the lower mass limit was obtained to be 1.17 TeV [123].

A targeted search for a T quark, produced singly in association with a light flavor quark and a b quark and decaying into bW, was carried out by CMS at $\sqrt{s}$=13 TeV and a dataset corresponding to 2.3 fb^{-1} [125]. The analysis used lepton+jets events, with at least one b-tagged jet with large transverse momentum, and a jet in the forward η region. Selected events were required to have $S''_T > 500$ GeV, where S''_T is defined as the scalar sum of the transverse momenta of the lepton, the leading central jet, and the missing transverse momentum. The invariant mass of the T candidate was used as the discriminating variable and was reconstructed using the four-vectors of the leptonically decaying W boson and the leading central jet. No excess over the standard model prediction was observed. As the VLQ width is proportional to the square of the coupling, upper limits were set on the production cross section assuming a narrow width VLQ with coupling greater than 0.5. For Y/T quarks with a coupling of 0.5 and a 100% branching fraction for the decay to bW the excluded masses were in the range from 0.85 to 1.40 TeV [125]. A similar search [126, 127] was performed by ATLAS for a singly produced T or $Y_{-4/3}$ quark decaying to Wb using a dataset corresponding to 36.1 fb^{-1}. The search was performed using lepton+jets events with a high p_T b-tagged jet, and at least one forward jet. The reconstructed mass of the $T/Y_{-4/3}$ quark, was used as the discriminating variable and showed no excess above the expectation from SM. Interference effects with the SM background are included in the study. This search led to 95% CL upper limits on the mixing angle $|sin(\theta_L)|$ (C_L^{Wb}) in the range of 0.18–0.35 (0.25–0.49) for singlet T quark mass between 0.8–1.2 TeV. This search

also provided limits as a function of the $Y_{-4/3}$ quark mass, on the coupling of the $Y_{-4/3}$ quark to bW, and the mixing parameter $|sin\theta_R|$ (C_R^{Wb}) for a (B,$Y_{-4/3}$) doublet model [126]. For VLQ masses between 0.08–1.8 TeV, the limits on $|sin(\theta_R)|$ (C_R^{Wb}) are in the range 0.17–0.55 (0.24–0.77), and for for $Y_{-4/3}$ quark mass between 0.9–1.25 TeV, the limits on $|sin\theta_R|$ are around 0.18–0.19 and below the constraints from electroweak precision observables. For $Y_{-4/3}$ quark in the triplets (T,B,$Y_{-4/3}$), limits on $|sin(\theta_L)|$ (C_L^{Wb}) are between 0.16–0.39 (0.31–0.78) for masses between 0.8 GeV–1.6 TeV [126].

$T \to tH^0$:

ATLAS has performed a search for $T\overline{T}$ production with $T \to tH^0$ [124, 128]. Given the dominant decay mode $H^0 \to b\bar{b}$, these events are characterized by a large number of jets, many of which are b-jets. Thus the event selection required one isolated electron or muon and high jet multiplicity (including b-tagged jets). The sample is categorized by the jet multiplicity (5 and $\geq$6 jets in the 1-lepton channel; 6 and $\geq$7 jets in the 0-lepton channel), b tag multiplicity (2, 3 and $\geq$4) and mass-tagged jet multiplicity (0, 1 and $\geq$2). The distributions of $m_{\rm eff}$, defined as the scalar sum of the lepton and jet p_T and the missing p_T, for each category were used as the discriminant for the final signal and background separation. No excess of events was found. Weak isospin doublet T quarks were excluded below 1.16 TeV.

A search by ATLAS for pair produced VLQs with an all-hadronic final state signature yields an exclusion of pure decays $T \to tH^0$ upto a T quark mass of 1.01 TeV [129]. This analysis used a deep neural network technique to identify jets originating from boosted bosons and top-quarks and is described further in subsection 92.2.3.2.

The CMS search for $T\overline{T}$ production, with $T \to tH^0$ decays has been performed in lepton+jets, multilepton and all-hadronic final states. The lepton+jets analysis [130] emphasizes the presence of a large number of b-tagged jets, and combines it with other kinematic variables in a Boosted Decision Tree (BDT) to enhance signal to background discrimination. The multilepton analysis [130] was optimized for the presence of b-jets and the large hadronic activity. For $\mathcal{B}(T \to tH^0) = 1$, the combined lepton+jets and multilepton analyses led to a lower limit on T quark masses of 0.71 TeV. A search for $T \to tH^0$ in all-hadronic decays [131], optimized for a high mass T quark, and based on identifying boosted top quark jets has been carried out by CMS. This search aimed to resolve subjets within the jets arising from boosted top quark decays, including b tagging of the subjets. A likelihood discriminator was defined based on the distributions of H_T and the invariant mass of the two b-jets in the events for signal and background. No excess above background expectations was observed. Assuming 100% branching ratio for $T \to tH^0$, this analysis led to a lower limit of 0.75 TeV on the mass of the T quark.

Searches for T quarks at $\sqrt{s}$=13 TeV, based on a 2.6 fb^{-1} dataset [132] have been performed by CMS using the lepton+jets final state. This search has been optimized for high mass T quarks by exploiting techniques to identify W or Higgs bosons decaying hadronically with large transverse momenta. The boosted W channel excluded T quarks decaying only to bW with masses below 0.91 TeV, and the boosted tH channel excluded T quarks decaying only to tH for masses below 0.89 TeV.

A CMS search for $T \to tH^0$ with $H^0 \to \gamma\gamma$ decays has been performed [133] in pair production of T quarks. To identify the Higgs boson produced in the decay of the heavy T quark, and the subsequent $H^0 \to \gamma\gamma$ decay, the analysis focused on identification of two photons in events with one or more high p_T lepton+jets or events with no leptons and large hadronic activity. A search for a resonance in the invariant mass distribution of the two photons in events with large hadronic activity defined by the H_T variable showed no excess above the prediction from standard model processes. The analysis resulted in exclusion of T quark masses below 0.54 TeV.

A search for electroweak single production of T quarks decaying to tH^0 using boosted topologies in fully hadronic [134] and lepton+jets [135] in the final states has been performed by CMS. The electroweak couplings of the T quarks to the SM third generation quarks are highly model dependent, and hence these couplings determine the rates of the single T quark production. In both analyses, T quark invariant mass was reconstructed using the boosted Higgs boson jet and the top quark. Higgs boson jets were identified using jet substructure techniques and subjet b tagging. For the lepton+jets analysis, the top quark was reconstructed from the leptonically decaying W and the b jet, while in the all-hadronic analysis the top quark jet was tagged using substructure analysis. There was no excess of events observed above background. Exclusion limits on the product of the production cross section and the branching fraction ($\sigma(pp \to Tqt/b) \times \mathcal{B}(T \to tH^0)$ were derived for the T quark masses in the range 0.70-1.8 TeV. From the lepton+jets analysis, for a mass of 1.0 TeV, values of ($\sigma(pp \to Tqt/b) \times \mathcal{B}(T \to tH^0)$ greater than 0.8 and 0.7 pb were excluded assuming left- and right-handed coupling of the T quark to standard model fermions, respectively [135]. For the all-hadronic analysis, upper limits between 0.31 and 0.93 pb were obtained on ($\sigma(pp \to Tqt/b) \times \mathcal{B}(T \to tH^0)$ for T quark masses in the range 1.0-1.8 TeV [134].

$T \to tZ$:

Both ATLAS and CMS searched for T quarks that decay exclusively into tZ in pp collisions at $\sqrt{s} = 13$ TeV. No excesses were found in either search.

ATLAS performed a search [136] optimized for pair production of vector-like top quarks decaying into tZ where the Z boson subsequently decays into neutrino pairs, utilizing 36.1 fb^{-1} of data. The search selected events with one lepton, multiple jets, and significant missing transverse momentum. No significant excesses were found and lower limits on the mass of a vector like top quark were placed, excluding masses below 0.87 TeV (weak-isopsin singlet), 1.05 TeV (weak-isospin doublet), and 1.16 TeV (pure tZ mode).

Another search by ATLAS for pair produced T decaying to tZ has been carried out by reconstructing the high transverse momentum Z boson from a pair of opposite-sign same-flavor leptons, using events with two or three charged leptons [137]. The final analysis is based on three final state signatures. In the trilepton events, at least one b-tagged jet is required and S_T is used as the discriminating variable. In events with two leptons, at least 2 b-jets are requested and events with zero or one high p_T top-tagged jet, use H_T as the discriminator. The second dilepton analysis with two top-tagged high p_T jets focuses on hadronically decaying heavy resonances and the invariant mass of the Z boson and the highest p_T b-tagged jet is found to be a good discriminating variable. No excess was observed over the background expectations. The combined analysis yields a lower limit on T quark mass of 1.03 TeV (1.21 TeV) in the singlet (doublet) model or 100% branching ratio for $T \to tZ$ a lower limit on the T quark mass of 1.34 TeV is obtained.

ATLAS has subsequently carried out a search [138] for singly produced T quarks decaying to tZ where the Z boson decays into neutrino pairs. The search is carried out using 36.1 fb^{-1} of data in events with two different final state signatures: one with jets and significant missing p_T (0L) and the other with a single lepton, jets and missing p_T (1L). Events are divided into signal and dedicated W+jets and $t\bar{t}$ background control regions. The sensitivity to the T quark signal is extracted using distributions of missing p_T for the 1L and the distribution of T quark transverse mass constructed from missing p_T and the high p_T large-radius top-tagged jet, for 0L analysis. There is no excess found over the expected background and lower limits on the production of T singlets are obtained as a function of the left- and right-handed couplings $c_{L,W}$ and $c_{R,W}$ to top quarks and W bosons, where c_W above 0.7 is excluded for T quark mass of 1.4 TeV. The limits on c_W are also recasted into expected and observed 95% CL upper limits for the mixing angle (θ_L) of a singlet T with the top quark.

CMS searched [139] for single production of T quarks decaying into tZ with the Z boson decaying to pairs of charged leptons (electrons and muons) and the top quark decaying hadronically using 35.9 fb^{-1} of data. Limits were placed on T quarks with masses between 0.7 and 1.7 TeV excluding the product of cross section and branching fraction above values of 0.27 to 0.04 pb.

Additionally, limits on the product of cross section and branching fractions for a Z' boson decaying into tZ were set between 0.13 and 0.06 pb for Z' boson masses in the range from 1.5 to 2.5 TeV.

Similar searches by ATLAS for singly produced T decaying to Zt have been performed in final state signatures with two or three charged leptons [137]. The analysis relies on tagging b-jets and high p_T large-radius jets originating from top-quarks. Additional selections are devised to reduce the contributions from pair production of T quarks. For events with dilepton analysis, the discriminating variable is the mass of the T quark formed using the invariant mass of the Z boson candidate and the highest p_T top-tagged jet, while for the trilepton analysis, the variable S_T is used to search for an excess of data over the expected SM background. No excess above the SM expectations is observed. The two final states (dilepton and trileptons) are combined to obtain the final results. For the coupling parameter κ_T between 0.1–1.6, the 95% CL upper limits on the production cross section times branching fraction into Zt is between 0.16–0.18 (0.03–0.05) pb at T quark mass of 0.7 (2) TeV.

The search by the ATLAS experiment for VLQ pair production optimized to search for $T \to tZ$ decays [140] in a dataset with 139 fb^{-1} of luminosity has been performed in final states with either two leptons or three or more leptons. A multi-class boosted object tagger based on DNN techniques for large-radius jets is used to categorize events according to the number of high p_T boosted H^0, Z/W, and top quark jets. The discriminant in the signal to evaluate the sensitivity depends on the number of leptons in the event. For the two lepton analysis, the discriminant is the mass of the T quark which is constructed from b and Z candidates, while for the three or more lepton analysis, H_T computed using the p_T of the jets and leptons is used as the discriminant. This analysis excludes T quark masses up to 1.27 GeV (1.46 GeV), for the singlet (doublet) configuration [140].

Combination of $T \to tZ/tH^0$:

The search performed by the ATLAS experiment for electroweak single production of T quark decaying to tH^0 and tZ uses a dataset corresponding to 139 fb^{-1} of integrated luminosity, and events with a single lepton with multiple jets and b-jets in the final state [141]. The single production channel for VLQs probes κ, the universal coupling constant, which also controls the production cross section and the resonance width of the VLQ. The analysis uses techniques to tag boosted jets, and categorizes events by numbers of jets and b-jets. The event discriminant is the "effective mass" (meff) observable, defined as the scalar sum of the p_T of all central jets, p_T of leptons and the missing p_T in the event. No significant excess is observed. Limits on the mass of T quark and universal coupling strength (κ) are obtained. For singlet T quarks, values of κ above 0.5 are excluded for all masses below 1.8 TeV. For T quark mass of 1.6 TeV, κ above 0.41 is excluded [141].

A CMS search published in 2020 concentrates on the electroweak production of the T quark with $T \to tH^0$, and $T \to tZ$ decays, where subsequently both H^0 and Z Bosons decay hadronically, leading to fully hadronic final states [142]. The search focuses on evidence of T quarks produced in association with a b quark ($qg \to T\bar{b}q'$) or a top quark ($qg \to T\bar{t}q$). The production cross sections are model dependent, as the electroweak production depends on the strength of the T quark coupling, TbW (TtZ), for the charged-current (neutral-current) process, at the production vertex. The searches are split into two domains depending on the mass of the T quark and consider a wide range of widths of the T quark from a few percent to about 30% of the T quark mass. The event selection relies primarily on the large number of jets and on efficient identification of jets from b-quarks, in addition to double-b jet decays of the H^0 and Z bosons. The final sensitivity is derived by the search for a resonant peak in the tH^0/Z invariant mass spectrum. For low mass T quark searches, three independent regions based on the b-tagged jet requirements are examined. For T quark masses above 1 TeV, which result in highly Lorentz-boosted top quarks and H^0 or Z boson, large-area jets are used to form the T quark. This search reports upper limits at 95% confidence level on $\sigma B(T \to tH)$ and $\sigma B(T \to tZ)$ between 2 pb and 20 fb for T masses between 0.6 to 2.6 TeV in the Tbq and Ttq production channels. The analysis also reports combined results for $T \to tH$ and $T \to tZ$ associated production with a bottom quark and provides constraints on T quarks in the T singlet model for masses below 1.00 TeV. For an expected fractional width of 30%, the expected sensitivity extends to 1.28 TeV, comparable to the most stringent results.

Combination of $T \to bW/tZ/tH^0$:

Most of the analyses described above target an individual decay mode of the T quark, with 100% branching ratio to either bW, tZ or tH^0 and are optimized accordingly. However, they have varied sensitivity to all three decay modes and the results can be interpreted as a function of branching ratios to each of the three decay modes, assuming the total adds up to unity ($\mathcal{B}(tH) + \mathcal{B}(tZ) + \mathcal{B}(Wb) = 1$).

Combinations of analyses have been performed by both ATLAS and CMS. The limits set by ATLAS searches in $W(\ell\nu)b + X, H(bb)b + X, Z(\nu\overline{\nu}), Z(\ell\ell)t/b + X$, dileptons with same-sign charge, trileptons, all-hadronic final states have been combined and the results obtained for various sets of branching fractions for T quark decays to bW, tH^0 and tZ are shown in Fig. 92.3 (left). In the combined analysis, ATLAS sets lower T quarks mass limit of 1.31 TeV for all possible values of the branching fractions to the three decay modes [123,136,143]. In Fig. 92.3, exclusion is shown in the plane of $\mathcal{B}(T \to Ht)$ versus $\mathcal{B}(T \to Wb)$, for different values of the T quark mass. The default branching ratio values for the weak-isospin singlet and doublet cases are also shown in Fig. 92.3 as yellow circle and star symbols respectively. Assuming a weak isospin (T,B) doublet and $|V_{Tb}| << |V_{tB}|$, T quark mass below 1.37 TeV is excluded.

A CMS analysis for pair production of T combines three channels with lepton final states: single lepton, two leptons with the same sign of the electric charge (SS), or at least three leptons (trilepton) [144]. For various combinations of branching fractions for T quark decays to bW, tH^0 and tZ, the combined results exclude T quarks with masses below 1.14–1.3 TeV and are shown in Figure 92.3 (right). Single lepton events are classified into 16 signal categories and 6 background control regions based on multiplicity of b-tagged, high p_T H^0 and W-tagged jets. The discriminating variables are H_T for H^0-tagged events and the minimum invariant mass constructed from the lepton and the b jet, min[M_{lb}], for zero H^0-tagged events. For the same-sign dilepton and trilepton analyses, the non-prompt backgrounds due to misidentified jets and leptons are derived from data control regions. In the trilepton analysis the S_T variable is used as the signal discriminator binned in four categories based on the lepton flavor combinations (eee, $ee\mu$, $e\mu\mu$, $\mu\mu\mu$). The single lepton analysis is most sensitive for $tHbW$ and $WbWb$ decay modes, within the SS dilepton analysis $tHtH$ and $tHtZ$ have the best efficiency and for trileptons the $tZtZ$ and $tHtZ$ decays modes have the highest efficiency. CMS excludes singlet (doublet) T quark masses below 1.2 (1.28) TeV. Masses below 800 GeV were excluded in previous searches. For T quark masses in the range 0.8–1.8 TeV, cross sections smaller than 30.4–9.4 fb (21.2–6.1 fb) are excluded for the singlet (doublet) scenario.

Another inclusive search for pair produced T in the all-hadronic final state [122] has been performed by CMS using the boosted event shape tagger (BEST) neural network technique to classify jets in six categories W, Z, H^0, t, b, and light. This search does not focus on a given VLQ mode, but on various combinations of the boson and quark jets in the final state. Anti-k_T jets with a distance parameter of 0.8 are used. The BEST NN algorithm simultaneously classifies jets according to heavy object type. For each of the six particle hypotheses, it boosts each jet constituent into corresponding frame along the jet momentum direction, and calculates event shape and angular variables in the boosted frame, with the expectation that when boosting to the correct rest frame, jet constituents will be isotropic and show the expected N-prong structure of the decaying object in its rest frame. A neural network is trained using the event shape and angular variables in the boosted frame to classify jets according to one of those six possibilities (W, Z, H, t, b, or light). The analysis bins the events into 126 categories depending on the number of W, Z, H, t, b, or light jets in the final state with a maximum of four such objects. For

each category $H_T^{\rm AK8}$, the scalar sum of p_T of all AK8 jets, is used as the signal discriminator. A scan over a combination of various branching fractions is also performed. This search excludes T quark masses in the range 0.74–1.37 TeV for the tH decay mode in the NN analysis.

An inclusive search for VLQs has been carried out by CMS targeted at heavy T quarks decaying to any combination of bW, tZ, or tH^0 as described in [130]. Selected events have at least one isolated charged lepton. Events were categorized according to number and flavor of the leptons, the number of jets, and the presence of hadronic vector boson and top quark decays that are merged into a single jet. The use of jet substructure to identify hadronic decays significantly increases the acceptance for high T quark masses. No excess above standard model backgrounds was observed. Limits on the pair production cross section of the new quarks are set, combining all event categories, for all combinations of branching fractions into the three final states. For T quarks that exclusively decay to $bW/tZ/tH^0$, masses below 0.70/0.78/0.71 TeV are excluded.

92.2.3.2 *Searches for* $\boldsymbol{B}$ *quarks that decay to* $\boldsymbol{W}$, $\boldsymbol{Z}$ *and* $\boldsymbol{H^0}$ *bosons*

ATLAS and CMS have performed searches for pair production of heavy B quarks which subsequently decay to Wt, bZ or bH^0. The searches have been carried out in final states with single leptons, dileptons (with same charge or opposite charge), multileptons, as well as in fully hadronic final states.

$B \to bH^0$:

A search for B pair-produced events has been performed by the CMS experiment [123] using 137 fb^{-1} of data where the B decays into a $b/\overline{b}$ quark and either a H^0 or a Z boson. This search concentrates on final states with fully hadronic signatures, and utilizes different jet multiplicity categories to account for two resolved jets or merged single jets from H^0 or Z boson to $b\overline{b}$ decays, depending on the p_T of the H^0 or Z bosons. Nine final state categories are used, depending on the number of observed jets and the reconstructed event mode. No significant excess over expected background is observed. For the case $\mathcal{B}(B \to bH) = 100\%(50\%)$, VLQs with masses below 1.57 (1.45) TeV are ruled out.

Using 36.1 fb^{-1} of data, ATLAS has performed a search for pair produced VLQs with all-hadronic final state signature [129]. While this analysis provides exclusion limits for all third generation VLQs, it provides the strongest results for the $B \to bH^0$ decay mode and excludes decays with $\mathcal{B}(\mathcal{B} \to \lfloor\mathcal{H}') = \infty$.ı scenario for B masses upto 1.01 TeV. The limits are also cast in a two-dimensional plane of branching ratio values of $B \to bH^0$ vs. $B \to Wb$. This analysis required the presence of high p_T jets and multiple b tags. It used a multi-class DNN to classify jets arising from W, Z, H^0 bosons and top-quarks. In addition, the matrix element method was used to compute the likelihood for the event to arise from a particular VLQ final state and to construct the final discriminator. To increase the sensitivity of the analysis, processes with the same number of top quarks, W/Z bosons, and H^0 Higgs bosons are combined into a single hypothesis.

The ATLAS experiment has performed a search for single production of a vector-like B quark decaying to a b-quark and a H^0 boson, with $H^0 \to b\overline{b}$ decay, using a dataset corresponding to an integrated luminosity of 139 fb^{-1} [145]. The all hadronic final state signature relies on identification of at least 3 b-jets, with an additional soft forward jet from the spectator quark. Large area jets are used to identify boosted H^0 decays. This analysis results in excluding the single production of a VLQ (B, Y) doublet with relative width larger than 5% between masses of 1.0 TeV and 1.76 TeV [145].

$B \to Wt$:

A search for $B \to tW$ in B pair produced events has been performed by the ATLAS experiment [123] using lepton+jets events with one hadronically decaying W and one leptonically decaying W utilizing 36.1 fb^{-1} of data at $\sqrt{s} = 13$ TeV. The search was optimized for T production decaying into Wb. Since the analysis was optimized for $T \to Wb$ rather than Wt decays the analysis does not reconstruct the full B mass. As discussed earlier, the hadronically and leptonically decaying heavy quarks were required to have similar reconstructed masses (within 300 GeV). The interpretation of the $T \to Wb$ in the context of $B \to tW$ production led to the exclusion of heavy B like VLQs for masses less than 1.25 TeV and 1.08 TeV, assuming a 100% branching fraction to tW or SU(2) singlet B scenario, respectively.

A similar search by CMS [146], using 19.8 fb^{-1} of $\sqrt{s} = 8$ TeV data, selected events with one lepton and four or more jets, with at least one b-tagged jet, significant missing p_T, and further categorized them based on the number of jets tagged as arising from the decay of boosted W, Z or H^0 bosons. The S_T distributions of the events in different categories showed no excess of events above the expected background and yielded a lower limit on the B quark mass of 0.73 TeV for $BR(B \to Wt) = 1$.

CMS [132] also searched for pair production of both TT and BB with collisions from 2.5 fb^{-1} of $\sqrt{s} = 13$ TeV data. The analysis searches for events with one high p_T lepton , multiple jets, and highly boosted W or Higgs bosons decaying hadronically. The analysis focuses on pair production and selects events with either a boosted W or Higgs candidate and then proceeds to search for anomalous production in excess of standard model production. Seeing no significant excesses CMS then proceeded to set limits in many different interpretations. The strongest was from the $B \to Wt$ interpretation leading to excluding heavy vector-like B quarks with mass less than 0.73 TeV.

The all-hadronic inclusive analysis [122] performed by CMS using the BEST NN technique to classify $W/Z/H^0/t/b$/light jets also gives exclusion limits on B quark production for various combinations of branching fractions for decays to tW, bZ, bH^0. By considering categories based on various combinations of the boson and quark jets in the final state it excludes B quarks with masses up to 1230 GeV, for B decays to tW with a 100% branching fraction.

Electroweak production of single heavy B+b production has been studied by CMS in the decay to tW with the lepton+jets final state [147]. Single lepton events with hadronic jets, including a forward jet, and missing p_T are selected and divided into 10 different categories based on lepton flavor (e/μ), top-tagged, W-tagged, and 0/1/2 b-tagged jets. The B quark mass m_{reco} is fully reconstructed from lepton, jets, and missing p_T, where the neutrino four-momentum is computed using the missing p_T and the W mass constraint. For events within the top-tagged category, the high p_T top-tagged hadronic jet and the leptonically decaying W boson are used to compute m_{reco}. The m_{reco} distribution are used as the signal discriminator. In the absence of an excess over the expected SM background, the exclusion limits on the production cross section for B quark masses between 0.7-2 TeV varies between 0.3 to 0.03 pb. In addition, B quarks with left-handed couplings and a relative width of 10, 20, and 30% are excluded for masses below 1.49, 1.59, and 1.66 TeV respectively.

$B \to bZ$:

As mentioned above, a search for B pair produced events, with final states with fully hadronic signature, using 137 fb^{-1} of data, has been performed by the CMS experiment [123]. In this search, the B decays into a $b/\overline{b}$ quark and either a H^0 or a Z boson. For the case $\mathcal{B}(B \to bZ) = 100\%(50\%)$, VLQs with masses below 1.39 (1.45) TeV are ruled out by this analysis.

A search by CMS [148] for the pair-production of a heavy B quark and its antiparticle has been performed, where one of the heavy B quark decays to bZ. Events with a Z boson decaying to e^+e^- or $\mu^+\mu^-$ and at least one b jet are selected. The signal from $B \to bZ$ decays is expected to appear as a local enhancement in the bZ mass distribution. No such enhancement was found and B quarks that decay 100% into bZ are excluded below 0.70 TeV. This analysis also set upper limits on the branching fraction for $B \to bZ$ decays of 30-100% in the B quark mass range 0.45-0.70 TeV. A complementary search has been carried out by ATLAS for new heavy quarks decaying into a Z boson and a b-quark [149]. Selected dilepton events contain a high transverse momentum Z boson that decays leptonically, together with two b-jets. If the dilepton events have an extra lepton in addition to those from the Z boson, then only one b-jet is required. No significant excess of events above the standard model expectation

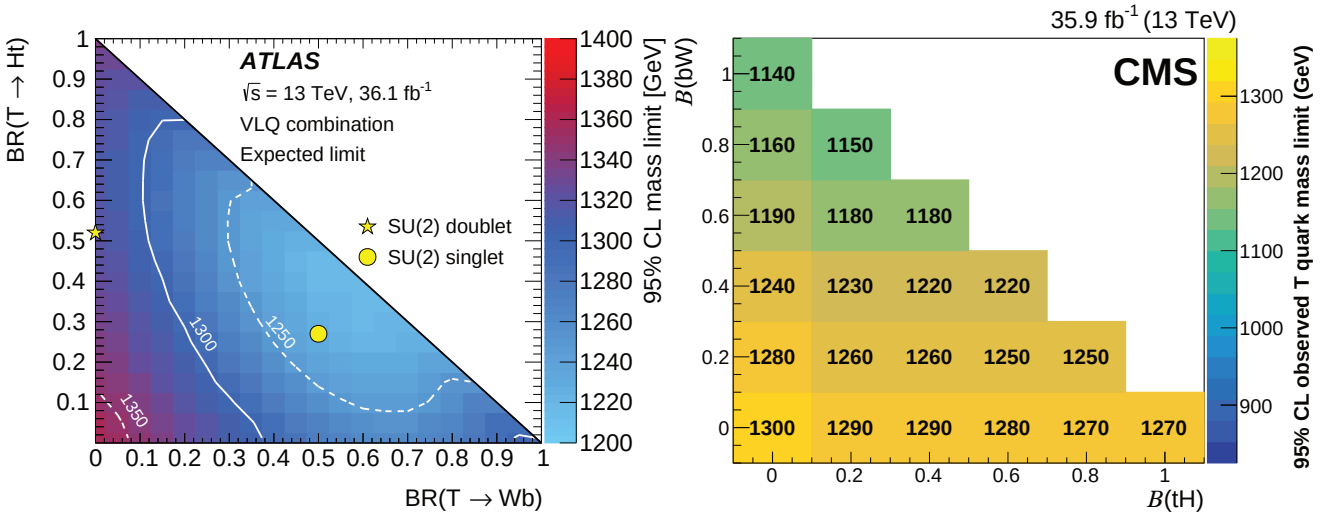

Figure 92.3: Left panel: observed limits on the mass of the T quark in the plane of $\mathcal{B}(T \to tH^0)$ versus $\mathcal{B}(T \to bW)$ from a combination [143] of all ATLAS searches for TT production. The markers indicate the default branching ratios for the SU(2) singlet and doublet scenarios. Right panel: the observed lower limits on the T quark mass (in GeV), from CMS searches after combining all lepton channels [144], for various branching fraction scenarios. $\mathcal{B}(T \to Wb) + \mathcal{B}(T \to tZ) + \mathcal{B}(T \to tH^0) = 1$ is assumed.

was observed, and mass limits were set depending on the assumed branching ratios, as shown in Fig. 92.4. In a weak-isospin singlet scenario, a B quark with mass lower than 0.65 TeV was excluded, while for a particular weak-isospin doublet scenario, a B quark with mass lower than 0.73 TeV was ruled out.

The search by the ATLAS experiment for $B \to bZ$ decays [140] in final states with either two leptons or three or more leptons using a multi-class boosted object tagger to categorize events according to the number of high p_T boosted H^0, Z/W, and top quark jets excludes B quark masses up to 1.20 GeV (1.32 GeV), for the singlet (doublet) configuration [140].

In addition to pair production, ATLAS has also searched for the electroweak production of single B quarks, which is accompanied by a b-jet and a light jet [149]. The dilepton selection for double B production was modified for the single B production study by requiring the presence of an additional energetic jet in the forward region. An upper limit of 200 fb was obtained for the process $\sigma(pp \to B\bar{b}q) \times B(B \to Zb)$ with a heavy B quark mass at 0.70 TeV. This search indicated that the electroweak mixing parameter X_{Bb} below 0.5 is neither expected nor observed to be excluded for any values of B quark mass.

Combination of $B \to tW/bZ/bH^0$:

The ATLAS experiment has combined the various analyses targeted for specific decay modes to obtain the most sensitive limit on the pair production of B quarks [123, 124, 143]. Various searches $(W(\ell\nu)t + X, Z(\ell\ell)t/b + X$, same sign charge dilepton events, trilepton events, and all-hadronic) are combined to obtain lower limit on the mass of the B quark [in the plane of $BR(B \to Wt)$ vs $BR(B \to bH)$]. The searches were optimized for 100% branching fractions and hence are most sensitive at large $BR(B \to Wt)$, and also at large $BR(B \to bH^0)$. For all possible values of branching ratios in the three decay modes tW, bZ, or bH^0, the lower limits on the B quark mass was found to be 1.03 TeV and shown in Fig. 92.4 (left) as a function of the B quark branching ratios.

CMS combined three channels with lepton final states: single lepton, two leptons with the same sign of the electric charge (SS), or at least three leptons (trilepton) [144]. For various combinations of branching fractions for B quark decays to tW, bH^0 and bZ, the combined results exclude b quarks with masses below 0.91–1.24 TeV and are shown in Figure 92.4 (right); the details are provided earlier in subsection 92.2.3.1. The single lepton analysis is most sensitive for $tHbW$ and $WbWb$ decay modes, within the SS dilepton analysis $tHtH$ and $tHtZ$ have the best efficiency and for trileptons the $tZtZ$ and $tHtZ$ decays modes have the highest efficiency. CMS excludes singlet (doublet) B quark masses below 1.17 (0.94) TeV. Masses below 800 GeV were excluded in previous searches. For B quark masses in the range 0.8–1.8 TeV, cross sections smaller than 40.6-–9.4 fb (101-–49.0 fb) are excluded for the singlet (doublet) scenario.

92.2.3.3 *Searches for top-partner quark* $\boldsymbol{X_{5/3}}$

Searches for a heavy top vector-like quark $X_{5/3}$, with exotic charge $\pm 5/3$, such as that proposed in Refs. [151, 152], have been performed by both ATLAS and CMS [123, 153].

The analyses assumed pair-production or single production of $X_{5/3}$ with $X_{5/3}$ decaying with 100% branching fraction to tW. Searches for $X_{5/3}$ have been performed using two final state signatures: same-sign leptons and lepton+jets.

The analysis based on searching for same-sign leptons, from the two W bosons from one of the $X_{5/3}$, has smaller backgrounds compared to the lepton+jets signature. Requiring same-sign leptons eliminates most of the standard model background processes, leaving those with smaller cross sections: $t\bar{t}W$, $t\bar{t}Z$, WWW, and same-sign WW. In addition, backgrounds from instrumental effects due to charge misidentification were considered. Assuming pair production of $X_{5/3}$, the analysis by CMS using H_T as the discriminating variable restrict the $X_{5/3}$ mass to be higher than 1.16 (1.10) TeV for a right (left) handed chirality particle [153–155]. The limits obtained by ATLAS, by classifying the signal region by number of b-jets, H_T, and missing p_T in the event, led to a lower mass limit on $X_{5/3}$ of 1.19 TeV [156, 157].

Searches for $X_{5/3}$ using leptons+jets final state signatures are based on either full or partial reconstruction of the T mass from the lepton, jets (including b-jets) and missing p_T. The CMS search [153, 158] also utilized jet substructure techniques to identify boosted $X_{5/3}$ topologies. The discriminating variable used was the mass constructed from the lepton and b-tagged jet, $M_{(\ell,b)}$, which corresponds to the visible mass of the leptonically decaying top quark. To optimize the search sensitivity, the events were further separated into categories based on lepton flavor (e, μ), the number of b-tagged jets, the number of W-tagged jets, and the number of t-tagged jets. In the absence of a signal, the CMS analysis excluded $X_{5/3}$ quark masses with right-handed (left-handed) couplings below 1.32 (1.30) TeV [158]. Combining the lepton+jets with the same-sign leptons analyses leads to a slight improvement and excludes $X_{5/3}$ quark masses with right-handed (left-handed) couplings below 1.33 (1.30) TeV.

The ATLAS lepton+jets search for $X_{5/3}$ utilized events with high p_T W bosons and b-jets. The search described earlier for T pair production, with $T \to Wb$ decays, can be reinterpreted as a search for $X \to tW$. This analysis excluded $X_{5/3}$ with masses below 1.25 TeV [123].

The single $X_{5/3}$ production cross section depends on the cou-

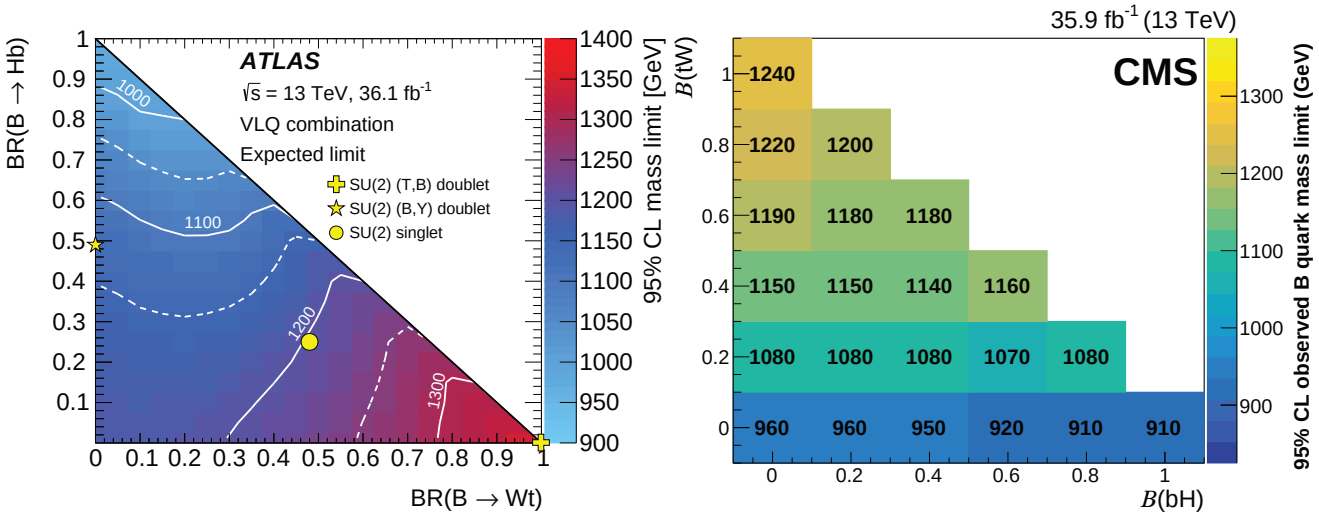

Figure 92.4: Observed limits on the mass of the B quark in the plane of $BR(B \to bH^0)$ versus $BR(B \to tW)$ from ATLAS searches [143] on the left panel, and CMS searches [144] on the right panel, for BB production. $\mathcal{B}(\mathcal{B} \to \mathcal{H}\rfloor)+\mathcal{B}(\mathcal{B} \to \lfloor\mathcal{Z})+\mathcal{B}(\mathcal{B} \to \mathcal{W}\sqcup) = 1$ is assumed. The yellow markers indicate the branching ratios for the SU(2) singlet and doublet scenarios.

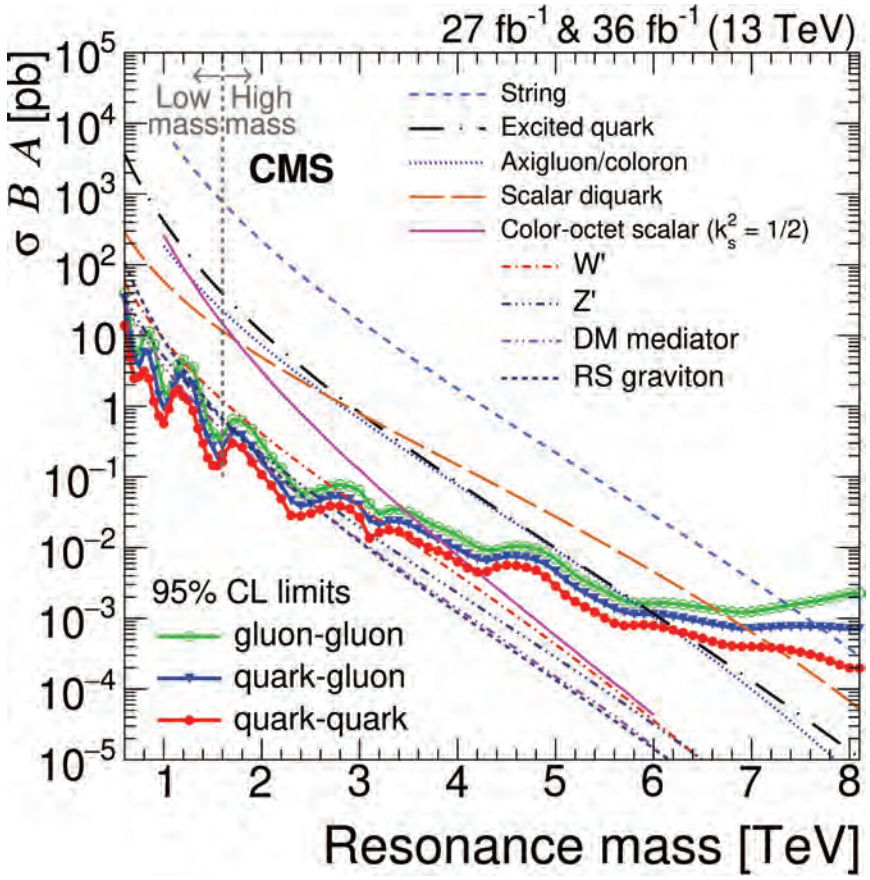

Figure 92.5: Observed 95% C.L. limits on $\sigma \times B \times A$ for string resonances, excited quarks, axigluons, colorons, E6 diquarks, s8 resonances, W' and Z' bosons, and Randall–Sundrum Gravitons g_{KK} from [150].

pling constant λ of the tWX vertex. ATLAS has performed an analysis of same-sign dileptons which includes both the single and pair production. This analysis led to a lower limit on the mass of the $X_{5/3}$ of 0.75 TeV for both values of $\lambda = 0.5$ and 1.0 [159].

Single heavy $X_{5/3}$+t production has been studied by CMS in the decay to tW with the lepton+jets final state [147]. The description of the analysis is provided earlier in the discussion of $B \to WtX$ decays, where the reconstructed mass of $X_{5/3}$, m_{reco} distribution is used as the signal discriminator. In the absence of an excess over the expected SM background, the exclusion limits on the production cross section for $X_{5/3}$ quark masses between 0.7–2 TeV varies between 0.3 to 0.03 pb, depending on the width of $X_{5/3}$ between 1–10%. In addition, $X_{5/3}$ quarks with left-handed couplings and a relative width of 10, 20, and 30% are excluded for masses below 0.92, 1.3, and 1.45 TeV respectively.

92.2.4 *Heavy resonances decaying to VLQ*

CMS has performed search for VLQ production in the decay of massive resonances such as Z' and W' bosons.

$\underline{Z' \to tT}$: Specifically searches are presented by CMS in Refs. [160] and [161] for massive spin-1 Z' resonances decaying to a top quark and a heavy VLQ top quark partner T. The results of this search for a heavy spin-1 resonance are interpreted in the context of two different models. In the $G^\star$ model which predicts ten VLQs ($T,\ B, \tilde{T}, \tilde{B}, T_{5/3}, T_{2/3}, T', B', B_{-1/3}, B_{-4/3}$) with the mass relationship $M(T_{5/3}) = M(T_{2/3}) = M(T)\cos(\phi_L)$. For the benchmark scenario [162], $\cos(\phi_L)$=0.84 and the branching fractions $T \to tH^0, tZ, Wb$ are 0.25, 0.25 and 0.5 respectively. The ρ^0 model predicts a multiplet of four new VLQs $T, B, X_{2/3}, X_{5/3}$, and in the benchmark scenario [163], the branching fractions $T \to tH^0, tZ, Wb$ are 0.5, 0.5 and 0 respectively.

Two of the three decays of the $Z' \to tT$ with $T \to tH^0, tZ, Wb$ are characterized by the presence of two top quark decays and a boson (H^0/Z). A search [161] by CMS, optimized for $T \to tH/Zt$ decays was carried out in the lepton+jets final state using a dataset corresponding to an integrated luminosity of 35.9 fb^{-1}. Jet substructure techniques are used to identify (or tag) the high p_T large-radius jets originating from H^0, Z bosons and merged top quarks. The mass of the Z' boson is used as the signal discriminator and constructed using H^0 or Z-tagged dijet, the hadronic and leptonic top quark four vectors. For the leptonic top quark reconstruction ($t \to b\ell\nu_\ell$), the neutrino four vector is obtained from the event missing p_T using the W boson mass constraint. While the high p_T hadronic top quark jets from decays of massive Z' bosons are mostly merged and identified by top tagging techniques, those from T decays maybe resolved. The reconstructed Z' candidate events are classified into six different categories requiring the presence of either a H^0-tagged jet with 2 b-tagged subjets or one b-tagged subjet or a Z-tagged boson, each with either zero or one top-tagged jet. This search does not observe any significant deviation in data over the expectation from standard model backgrounds. Within the context of the $G^\star$ model, for a T mass of 1.2 (1.5) TeV, this search excludes $G^\star$ [162] resonances with masses between 1.5–2.3 (2.0–2.4) TeV.

The search in the all-hadronic final state is based on a 2.6 fb^{-1} dataset [160], and optimized for $T \to Wb$ decays. Jet substructure techniques are deployed for tagging jets from high p_T W boson and top quarks. Events are categorized into two groups based on the presence of b-tagged subjets in the top-tagged jet. The multijet background estimation is challenging and determined using side-bands defined by inverting the b-tagging requirement. Upper limits on the cross section for $Z' \to tT$ are obtained in the range of 0.13–10 pb.

$\underline{W' \to Tb/Bt}$: W' bosons are predicted to decay to VLQ third generation partners $T,\ B$ quarks within composite Higgs and warped extra dimensional models [164]. In the benchmark scenarios of this framework, W' decays to Tb or Bt are equally distributed and the subsequent VLQ decays $T \to tH$ and $B \to bH^0$ each are assumed to have a branching fraction of 0.5. The search for $W' \to Tb/bH^0 \to tbH^0$ is performed using a sample of 35.9 fb^{-1} by CMS [165] in the final state with all-hadronic decays of both the Higgs boson ($H^0 \to b\bar{b}$) and the top quark. Both the H^0 boson and the top quark are expected to be boosted in the decay of a heavy W', and hence jet substructure techniques, including subjet b-tagging and double b-tagging are deployed to identify the H^0-tagged and the top-tagged jets. The three particle mass m_{tbH^0}, is used as the signal discriminant to observe the W' resonance. There is no excess observed in data above the expected SM background. This search excludes W' production cross section above 0.01–0.43 pb for masses between 1.5–4.0 TeV.

92.2.5 *Colorons and Colored Scalars*

These particles are associated with top-condensate and top-seesaw models, which involve an enlarged color gauge group. The new particles decay to dijets, $t\bar{t}$, and $b\bar{b}$.

Direct searches for colorons, color-octect scalars and other heavy objects decaying to $q\bar{q}$, qg, qq, or gg have been performed using LHC data from pp collisions at $\sqrt{s}$ =7, 8 and 13 TeV. Based on the analysis of dijet events from a data sample corresponding to a luminosity of 19.6 fb^{-1}, at $\sqrt{s} = 8$ TeV, the CMS experiment excluded pair production of colorons with mass between 1.20−3.60 and 3.90 − 4.08 TeV [166]. Analyses of inclusive 8- and 10-jet final states with low missing transverse momentum by CMS [167], set limits in several benchmark models. Colorons (axigluons) with masses between 0.6 and 0.75 (up to 1.15) TeV were excluded, and gluinos in R-parity violating supersymmetric scenarios were ruled out from 0.6 up to 1.1 TeV.

A search for pair-produced colorons based on an integrated luminosity of 5.0 fb^{-1} at $\sqrt{s} = 7$ TeV by CMS excluded colorons with masses between 0.25 TeV and 0.74 TeV, assuming colorons decay 100% into $q\bar{q}$ [168]. This analysis was based on events with at least four jets and two dijet combinations with similar dijet mass. Color-octet scalars (s8) with masses between 1.20−2.79 TeV were excluded by CMS [166], and below 2.7 TeV by ATLAS [169].

These studies have now been extended to take advantage of the increased center-of-mass energy during Run 2 of the LHC. Using 35.9 fb^{-1} of data collected at $\sqrt{s}$ =13 TeV, searches for narrow resonances have been performed by CMS. An analysis of the dijet invariant mass spectrum formed using wide jets [150, 170, 171], separated by $\Delta\eta_{jj} \leq 1.3$, led to limits on new particles decaying to parton pairs (qq, qg, gg). Specific exclusions on the masses of colorons and color-octet scalars were obtained and are shown in Fig. 92.5. Exclusions have been obtained for axigluons and colorons below 6.1 TeV, and color-octet scalars below 3.4 TeV.

Additional searches for dijet resonances have been performed by both ATLAS [172–174] and CMS [175, 176], though they have not been interpreted in the context of coloron production.

92.3 Conclusions

As the above analyses have demonstrated, there is already substantial sensitivity to possible new particles predicted to accompany the H^0 in dynamical frameworks of electroweak symmetry breaking. No significant hints of any deviations from the standard model have been observed, and limits typically at the scale of a few hundred GeV to a few TeV are set.

Given the need to better understand the H^0 and to determine in detail how it behaves, such analyses continue to be a major theme of Run 3 of the LHC, and we look forward to increased sensitivity as a result of the higher luminosity at the increased center of mass energy of collisions.

93. Grand Unified Theories

Revised August 2019 by A. Hebecker (Heidelberg U.) and J. Hisano (KMI, Nagoya U.).

93.1 The standard model

The Standard Model (SM) may be defined as the renormalizable field theory with gauge group $G_{SM} = SU(3)_C \times SU(2)_L \times U(1)_Y$, with 3 generations of fermions in the representation

$$(\mathbf{3},\mathbf{2})_{1/3} + (\bar{\mathbf{3}},\mathbf{1})_{-4/3} + (\bar{\mathbf{3}},\mathbf{1})_{2/3} + (\mathbf{1},\mathbf{2})_{-1} + (\mathbf{1},\mathbf{1})_{2}\ , \quad (93.1)$$

and a scalar Higgs doublet H transforming as $(\mathbf{1},\mathbf{2})_1$. Here and below we use boldface numbers to specify the dimension of representations of non-Abelian groups (in this case fundamental and antifundamental) and lower indices for $U(1)$ charges. The fields of Eq. (93.1) should also be familiar as $[Q, u^c, d^c, L, e^c]$, with $Q = (u, d)$ and $L = (\nu, e)$ being the quark and lepton $SU(2)$-doublets and u^c, d^c, e^c charge conjugate $SU(2)$-singlets.[1] Especially after the discovery of the Higgs, this model is remarkably complete and consistent with almost all experimental data.

A notable exception are neutrino masses, which are known to be non-zero but are absent in the SM even after the Higgs acquires its vacuum expectation value (VEV). The minimalist attitude is to allow for the dimension-five operator $(HL)^2$ [1], which induces (Majorana) neutrino masses. In the seesaw mechanism [2–4] this operator is generated by integrating out heavy singlet fermions (right-handed (r.h.) neutrinos). Alternatively, neutrinos can have Dirac masses if light singlet neutrinos are added to the SM spectrum.

Conceptual problems of the SM include the absence of a Dark Matter candidate, of a mechanism for generating the baryon asymmetry of the Universe, and of any reason for the observed smallness of the θ parameter of QCD (θ_{QCD}). In addition, the apparently rather complex group-theoretic data of Eq. (93.1) remains unexplained. Together with the abundance of seemingly arbitrary coupling constants, this disfavors the SM as a candidate fundamental theory, even before quantum gravity problems arise at energies near the Planck mass M_P.

To be precise, there are 19 SM parameters which have to be fitted to data: Three gauge couplings[2] g_3, g_2 and g_1, 13 parameters associated with the Yukawa couplings (9 charged fermion masses, three mixing angles and one CP phase in the CKM matrix.), the Higgs mass and quartic coupling, and θ_{QCD}. In addition, Majorana neutrinos introduce 3 more masses and 6 mixing angles and phases. As we will see, the paradigm of grand unification addresses mainly the group theoretic data of Eq. (93.1) and the values of the three gauge couplings. In many concrete realizations, it then impacts also the other mentioned issues of the SM, such as the family structure and fermion mass hierarchy.

More specifically, after precision measurements of the Weinberg angle θ_W in the LEP experiments, supersymmetric GUTs (SUSY GUTs) have become the leading candidates in the search for 'Physics beyond the SM'. Supersymmetry (SUSY) is a symmetry between bosons and fermions which requires the addition of superpartners to the SM spectrum. If SUSY is motivated as a solution to the gauge hierarchy problem (i.e. to the naturalness or fine-tuning problem of the electroweak scale) [5], superpartners have to be present near the weak scale. SUSY GUTs [6] then lead to the prediction of θ_W, in good agreement with subsequent observations [7]. However, the non-discovery of new particles at the LHC puts into question the presence of new physics at the TeV scale in general and in particular of low-scale supersymmetry. Still, SUSY may be present just outside the presently explored energy domain.

The measured Higgs mass (125 GeV) is in principle consistent with this picture, assuming superpartners in the region of roughly 10 TeV. Such heavy superpartners then induce radiative corrections raising the Higgs mass above the Z boson mass m_Z [8, 9]. However, from the vantage point of the hierarchy problem, heavy superpartners are problematic: They also contribute to SUSY-breaking Higgs mass parameters and thereby to the Higgs potential, tending to raise the Z mass. As a result, the incarnation of SUSY in terms of the minimal supersymmetric SM (MSSM) is becoming questionable. Turning the logic around, one may say that compared to expectations based on the MSSM with superpartner masses below about 1 TeV, the measured Higgs mass value of 125 GeV is somewhat too high [10]. Independently, the LHC has disfavored light colored superpartners (which does not imply that *all* superpartners are heavy). These facts represent new hints for future work on SUSY GUTs or on GUTs without TeV-scale supersymmetry.

93.2 Basic group theory and charge quantization

93.2.1 $SU(4)_C \times SU(2)_L \times SU(2)_R$

Historically, the first attempt at unification was the Pati-Salam model with gauge group $G_{PS} = SU(4)_C \times SU(2)_L \times SU(2)_R$ [11]. It unifies SM fermions in the sense that one generation (plus an extra SM singlet) now comes from the $(\mathbf{4},\mathbf{2},\mathbf{1}) + (\bar{\mathbf{4}},\mathbf{1},\mathbf{2})$ of G_{PS}. This is easy to verify from the breaking pattern $SU(4)_C \to SU(3)_C \times U(1)_{B-L}$ together with the identification of SM hypercharge as a linear combination between $B - L$ (baryon minus lepton number) and the T_3 generator of $SU(2)_R$. This model explains charge quantization, that is, why all electric charges are integer multiples of some smallest charge in the SM. Concretely, the $\mathbf{4}$ and $\bar{\mathbf{4}}$ of $SU(4)_C$ identify lepton number as the 4th colour and the tracelessness of the diagonal generator implies that quark charges are expressed in terms of $1/N_c$ fractions of lepton charges. However, G_{PS} is not simple (containing three simple factors), and thus it does not predict gauge coupling unification.

93.2.2 $SU(5)$

Since G_{SM} has rank four (two for $SU(3)_C$ and one for $SU(2)_L$ and $U(1)_Y$, respectively), the rank-four group $SU(5)$ is the minimal choice for unification in a simple group [12]. The three SM gauge coupling constants derive from a universal coupling α_G at the GUT scale M_G. Explicitly embedding G_{SM} in $SU(5)$ is straightforward, with $SU(3)_C$ and $SU(2)_L$ corresponding e.g. to the upper-left 3×3 and lower-right 2×2 blocks, respectively, in traceless 5×5 matrices for $SU(5)$ generators of the fundamental representation. The $U(1)_Y$ corresponds to matrices generated by $\mathrm{diag}(-2/3, -2/3, -2/3, 1, 1)$ and hence commutes with $SU(3)_C \times SU(2)_L \subset SU(5)$. It is then easy to derive how one SM generation precisely comes from the $\mathbf{10} + \bar{\mathbf{5}}$ of $SU(5)$ (where $\mathbf{10}$ is the antisymmetric rank-2 tensor):

$$\mathbf{10}: \begin{pmatrix} 0 & u_b^c & -u_g^c & u_r & d_r \\ -u_b^c & 0 & u_r^c & u_g & d_g \\ u_g^c & -u_r^c & 0 & u_b & d_b \\ -u_r & -u_g & -u_b & 0 & e^c \\ -d_r & -d_g & -d_b & -e^c & 0 \end{pmatrix} \quad \text{and} \quad \bar{\mathbf{5}}: \begin{pmatrix} d_r^c \\ d_g^c \\ d_b^c \\ e \\ -\nu_e \end{pmatrix}. \quad (93.2)$$

In addition to charge quantization this structure explains why the l.h. quark and lepton states fall in $SU(2)_L$ doublets while the r.h. states are singlets.

Since $SU(5)$ has 24 generators, $SU(5)$ GUTs have 12 new gauge bosons known as X bosons (or X/Y bosons) in addition to the SM. X bosons form an $SU(3)_C$-triplet and $SU(2)_L$-doublet. Their interaction connects quarks and leptons such that baryon and lepton numbers are not conserved and nucleon decay is predicted. Furthermore, $U(1)_Y$ hypercharge is automatically quantized since it is embedded in $SU(5)$.

In order to break the electroweak symmetry at the weak scale and give mass to quarks and leptons, Higgs doublets are needed. In the minimal $SU(5)$ model, they can sit in either a $\mathbf{5}_H$ or $\bar{\mathbf{5}}_H$. The three additional states are referred to as color-triplet Higgs scalars. Their couplings also violate baryon and lepton numbers, inducing nucleon decay. In order not to violently disagree with the non-observation of nucleon decay, the triplet mass must be greater than $\sim 10^{11}$ GeV [13]. Moreover, in SUSY GUTs [6], in order to cancel anomalies as well as give mass to both up and down quarks, both Higgs multiplets $\mathbf{5}_H$ and $\bar{\mathbf{5}}_H$ are required. As we shall discuss later, nucleon decay now constrains the Higgs triplets to have

[1] In our convention the electric charge is $Q = T_3 + Y/2$ and all our spinor fields are left-handed (l.h.).

[2] Equivalently, the $SU(2)_L$ and $U(1)_Y$ couplings are denoted as $g = g_2$ and $g' = \sqrt{3/5}\, g_1$. One also uses $\alpha_s = \alpha_3 = (g_3^2/4\pi)$, $\alpha_{\rm EM} = (e^2/4\pi)$ with $e = g \sin\theta_W$ and $\sin^2\theta_W = (g')^2/(g^2 + (g')^2)$.

mass significantly greater than M_G in the minimal SUSY $SU(5)$ GUT since integrating out the Higgs triplets generates dimension-five baryon-number-violating operators [14]. The mass splitting between doublet and triplet in the $\mathbf{5}_H$ (and $\bar{\mathbf{5}}_H$) comes from their interaction with the $SU(5)$ breaking sector.

93.2.3 $SO(10)$

While $SU(5)$ allows for the minimal GUT models, unification is not complete: Two independent representations, **10** and $\bar{\mathbf{5}}$, are required for one SM generation. A further representation, an SU(5) singlet, has to be added to serve as r.h. neutrino in the seesaw mechanism. In this case, the r.h. neutrino masses are not necessarily related to the GUT scale. By contrast, a single **16**-dimensional spinor representation of $SO(10)$ accommodates a full SM generation together with an extra singlet, potentially providing a r.h. neutrino [15]. This is most easily understood from the breaking pattern $SO(10) \to SU(5) \times U(1)_X$ and the associated branching rule[3] $\mathbf{16} = \mathbf{10}_{-1} + \bar{\mathbf{5}}_3 + \mathbf{1}_{-4}$. Here the indices refer to charges under the $U(1)_X$ subgroup, which is orthogonal to $SU(5)$ and reflects the fact that $SO(10)$ has rank five. From the above, it is easy to see that $U(1)_X$ charges can be given as $2Y - 5(B-L)$. Intriguingly, all representations of $SO(10)$ are anomaly free in four dimensions (4d). Thus, the absence of anomalies in an $SU(5)$-GUT or a SM generation can be viewed as deriving from this feature.

We now describe in more detail how one family of quarks and leptons appears in the **16**. To understand this, recall that the Γ-matrices of the 10d Clifford algebra give rise to five independent, anticommuting 'creation-annihilation' operators $\Gamma^{a\pm} = (\Gamma^{2a-1} \pm i\Gamma^{2a})/2$ with $a = 1, ..., 5$. These correspond to five fermionic harmonic oscillators or "spin" 1/2 systems. The 32-dimensional tensor product of those is reducible since the 10d rotation generators $M_{mn} = -i[\Gamma^m, \Gamma^n]/4$ $(m, n = 1, ..., 10)$ always flip an even number of "spins". This gives rise to the **16** as displayed in Table 93.1. Next, one also recalls that the natural embedding of $SU(5)$ in $SO(10)$ relies on 'pairing up' the 10 real dimensions to produce 5 complex dimensions, $\mathbb{R}^{10} \equiv \mathbb{C}^5$, similarly to the paring up of Γ^ms used above. This makes it clear how to associate one $|\pm>$ system to each complex dimension of $SU(5)$, which explains the labeling of the "spin" columns in Table 93.1: The first three and last two "spins" correspond to $SU(3)_C$ and $SU(2)_L$, respectively. In fact, an $SU(3)_C$ rotation just raises one color index and lowers another, changing colors $\{r, g, b\}$, or changes relative phases between the three spin states. Similarly, an $SU(2)_L$ rotation raises one weak index and lowers another, thereby flipping the weak isospin from up to down or vice versa, or changes the relative phase between the two spin states. In this representation $U(1)_Y$ hypercharge is simply given by $Y = -2/3(\sum \text{color spins}) + (\sum \text{weak spins})$. $SU(5)$ rotations corresponding to X bosons then raise (or lower) a color index, while at the same time lowering (or raising) a weak index. It is easy to see that such rotations can mix the states $\{Q,\ u^c,\ e^c\}$ and $\{d^c, L\}$ among themselves and ν^c is a singlet. Since $SO(10)$ has 45 generators, additional 21 gauge bosons are introduced including the $U(1)_X$ above. The 20 new $SO(10)$ rotations not in $SU(5)$ are then given by either raising any two spins or lowering them. With these rotations, **1** and **5** are connected with **10**. The last $SO(10)$ rotation changes phases of states with weight $2(\sum \text{color spins}) + 2(\sum \text{weak spins})$, which corresponds to $U(1)_X$.

$SO(10)$ has two inequivalent maximal subgroups and hence breaking patterns, $SO(10) \to SU(5) \times U(1)_X$ and $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R$. In the first case, one can carry on breaking to $G_{SM} \subset SU(5)$ precisely as in the minimal $SU(5)$ case above. Alternatively, one can identify $U(1)_Y$ as an appropriate linear combination of $U(1)_X$ and the $U(1)$ factor from $SU(5)$, leading to the so-called flipped $SU(5)$ [17] as an intermediate step in breaking $SO(10)$ to G_{SM}. In the second case, we have an intermediate Pati-Salam model thanks to the branching rule $\mathbf{16} = (\mathbf{4}, \mathbf{2}, \mathbf{1}) + (\bar{\mathbf{4}}, \mathbf{1}, \mathbf{2})$. Finally, $SO(10)$ can break directly to the SM at M_G. Gauge coupling unification remains intact in the case of this 'direct' breaking and for the breaking pattern $SO(10) \to SU(5) \to G_{SM}$ (with $SU(5)$ broken at M_G). In the case of intermediate-scale Pati-Salam or flipped $SU(5)$ models, gauge coupling predictions are modified. The Higgs multiplets in the minimal $SO(10)$ come from the fundamental representation, $\mathbf{10}_H = \mathbf{5}_H + \bar{\mathbf{5}}_H$. Note, only in $SO(10)$ does the representation type distinguish SM matter from Higgs fields.

[3] Useful references on group theory in the present context include [16] and refs. therein.

Table 93.1: Quantum numbers of **16**-dimensional representation of $SO(10)$.

state	Y	Color	Weak	$SU(5)$	$SO(10)$
ν^c	0	$---$	$--$	**1**	**16**
e^c	2	$---$	$++$	**10**	
u_r	1/3	$+--$	$-+$		
d_r	1/3	$+--$	$+-$

u_r^c	$-4/3$	$-++$	$--$		
u_g^c	$-4/3$	$+-+$	$--$		
u_b^c	$-4/3$	$++-$	$--$		
d_r^c	2/3	$-++$	$++$	$\bar{\mathbf{5}}$	
d_g^c	2/3	$+-+$	$++$		
d_b^c	2/3	$++-$	$++$		
ν	-1	$+++$	$-+$		
e	-1	$+++$	$+-$		

93.2.4 *Beyond* $SO(10)$

Finally, larger symmetry groups can be considered. For example, the exceptional group E_6 has maximal subgroup $SO(10) \times U(1)$ [18]. Its fundamental representation branches as $\mathbf{27} = \mathbf{16}_1 + \mathbf{10}_{-2} + \mathbf{1}_4$. Another maximal subgroup is $SU(3)_C \times SU(3)_L \times SU(3)_R \subset E_6$ with branching rule $\mathbf{27} = (\mathbf{3}, \mathbf{3}, \mathbf{1}) + (\bar{\mathbf{3}}, \mathbf{1}, \bar{\mathbf{3}}) + (\mathbf{1}, \bar{\mathbf{3}}, \mathbf{3})$. Independently of any underlying E_6, the group $[SU(3)]^3$ with additional permutation symmetry Z_3 interchanging the three factors can be considered. This is known as "trinification" [19]. The $E_6 \to [SU(3)]^3$ breaking pattern has been used in phenomenological analyses of the heterotic string [20]. However, in larger symmetry groups, such as E_6, $SU(6)$, etc., there are now many more states which have not been observed and must be removed from the effective low-energy theory.

Intriguingly, the logic by which G_{SM} is a maximal subgroup of $SU(5)$, which together with $U(1)_X$ is a maximal subgroup of $SO(10)$, continues in a very elegant and systematic way up to the largest exceptional group. The resulting famous breaking chain $E_8 \to E_7 \to E_6 \to SO(10) \to SU(5) \to G_{SM}$ together with the special role played by E_8 in group and in string theory is a tantalizing hint at deeper structures. However, since all representations of E_8 and E_7 are real and can not lead to 4d chiral fermions, this is necessarily outside the 4d GUT framework.

93.3 GUT breaking and doublet-triplet splitting

In the standard, 4d field-theoretic approach to GUTs, the unified gauge group is broken spontaneously by an appropriate GUT Higgs sector. Scalar potentials (or superpotentials in SUSY GUTs) exist whose vacua spontaneously break $SU(5)$ or $SO(10)$. While these potentials are ad hoc (just like the Higgs potential in the SM), the most naive expectation is that all their dimensionful parameters are $O(M_G)$. In the simplest case of $SU(5)$, the **24** (adjoint) GUT Higgs develops a VEV along the G_{SM}-singlet direction as $\langle\Phi\rangle \propto \text{diag}(-2/3, -2/3, -2/3, 1, 1)$. In order for $SO(10)$ to break to $SU(5)$, the **16** or **126**, which have a G_{SM}-singlet with non-zero $U(1)_X$ charge, get a VEV.

The masses of doublet and triplet in the $\mathbf{5}_H$ (and $\bar{\mathbf{5}}_H$) generically split due to their coupling to the GUT Higgs. In addition, both the doublet and the triplet masses also get an equal contribution from an $SU(5)$-invariant GUT-scale mass term. Without any further structure, an extreme fine-tuning between two large effects is then necessary to keep the doublet mass at the electroweak scale. Supersymmetry plays an important role in for-

bidding large radiative correction to the doublet mass due to the non-renormalization theorem [5]. However, even in this case we have to fine tune parameters at tree level. This is the doublet-triplet splitting problem which, in the SUSY context, is clearly related the μ-term problem of the MSSM (the smallness of the coefficient of $\mu H_u\ H_d$).

Several mechanisms for natural doublet-triplet splitting have been suggested under the assumption of supersymmetry, such as the sliding singlet [21], missing partner [22], missing VEV [23], and pseudo-Nambu-Goldstone boson mechanisms [24]. Particular examples of the missing partner mechanism for $SU(5)$ [25], the missing VEV mechanism for $SO(10)$ [26, 27] and the pseudo-Nambu-Goldstone boson mechanism for $SU(6)$ [28] have been shown to be consistent with gauge coupling unification and nucleon decay. From the GUT-scale perspective, one is satisfied if the triplets are naturally heavy and the doublets are massless ($\mu \simeq 0$). There are also several mechanisms for resolving the subsequent issue of why μ is of order the SUSY breaking scale [29].[4] For a review of the μ problem and some suggested solutions in SUSY GUTs and string theory, see [30–33] and references therein.

In general, GUT-breaking sectors successfully resolving the doublet-triplet splitting problem, dynamically stabilizing all GUT-scale VEVs and allowing for realistic neutrino masses and Yukawa couplings (including the GUT-symmetry violation in the latter) require a number of ingredients. However, for validity of the effective theory, introduction of higher or many representations is limited, otherwise a Landau pole may appear below the Planck scale. In addition, GUTs are only effective theories below the Planck scale in the 4d field-theoretic approach. Since M_G is close to this scale, the effects of higher-dimension operators are not obviously negligible. In particular, operators including the GUT-breaking Higgs may affect low-energy predictions, such as quark and lepton masses.

Thus, especially in the context of GUT breaking and doublet-triplet splitting, models beyond 4d field theory appear attractive. While this is mainly the subject of the next section, some advantages can already be noted: In models with extra dimensions, in particular string constructions, GUT breaking may occur due to boundary conditions in the compactified dimensions [34–37]. No complicated GUT breaking sector is then required. Moreover, boundary conditions can give mass only to the triplet, leaving the doublet massless. This is similar to the 'missing partner mechanism' since the effective mass term does not 'pair up' the triplets from $\mathbf{5}_H$ and $\overline{\mathbf{5}}_H$ but rather each of them with further fields which are automatically present in the higher-dimensional theory. This can eliminate dimension-five nucleon decay (cf. Sec. 93.6).

93.4 String-theoretic and higher-dimensional unified models

As noted earlier, the GUT scale is dangerously close to the scale of quantum gravity. It may hence be necessary to discuss unified models of particle physics in the latter, more ambitious context. Among the models of quantum gravity, superstring or M-theory stands out as the best-studied and technically most developed proposal, possessing in particular a high level of internal, mathematical consistency. For our purposes, it is sufficient to know that five 10d and one 11d low-energy effective supergravity theories arise in this setting (cf. [38] and refs. therein).

Grand unification is realized most naturally in the context of the two 'heterotic' theories with gauge groups $\mathrm{E}_8\times\mathrm{E}_8$ and $SO(32)$, respectively [36, 39] (see [40] for some of the more recent results). Justified in part by the intriguing breaking path $\mathrm{E}_8 \to \cdots \to G_{SM}$ mentioned above, the focus has historically largely been on $\mathrm{E}_8\times\mathrm{E}_8$. To describe particle physics, solutions of the 10d theory with geometry $\mathbb{R}^{1,3} \times M_6$ are considered, where M_6 is a Calabi-Yau (CY) 3-fold (with 6 real dimensions) [36]. The background solution involves expectation values of higher-dimensional components of the $\mathrm{E}_8\times\mathrm{E}_8$ gauge fields. This includes both Wilson lines [34] and non-vanishing field-strength and leads, in general, to a reduced gauge symmetry and to chirality in the resulting 4d effective theory. The 4d fermions arise from 10d gauginos.

Given an appropriate embedding[5] of G_{SM} in $\mathrm{E}_8\times\mathrm{E}_8$, gauge coupling unification is automatic at leading order. Corrections arise mainly through (string)-loop effects and are similar to the familiar field-theory thresholds of 4d GUTs[6] [41]. Thus, one may say that coupling unification is a generic prediction in spite of the complete absence[7] of a 4d GUT at any energy scale. This absence is both an advantage and a weakness. On the up side, GUT breaking and doublet-triplet splitting [43] are more naturally realized and dimension-five nucleon decay is relatively easy to avoid. On the down side, there is no reason to expect full GUT representations in the matter sector and flavor model building is much less tied to the GUT structure than in 4d.

Let us pause to explain the beautiful idea behind the advertised solution of the doublet-triplet splitting problem: One starts with a simply connected CY X and mods out the action of a discrete group G (say $\mathbb{Z}_2$). In the absence of fixed points, X/G is smooth and has a non-contractible 1-cycle. Furthermore, let G also act on the gauge bundle, according to an embedding $G \to \mathrm{E}_8$. Now the parallel transport around the 1-cycle is tied to a gauge rotation (one says a non-trivial Wilson-line is present). Moreover, this Wilson line can not be continuously turned off since, e.g. in the case of $\mathbb{Z}_2$, its square is the unit element of the group. The induced 'Wilson-line breaking', which comes on top of the breaking by non-zero field strengths, may remove certain sub-representations (e.g. the triplet of $SU(5) \to G_{SM}$) while keeping others exactly massless. A simpler and, due to fixed points, singular version of this will appear below in the context of orbifold GUTs.

One technical problem of heterotic constructions is the dependence on the numerous size and shape parameters of M_6 (the so-called moduli), the stabilization of which is poorly understood (see [44] for recent developments). Another is the sheer mathematical complexity of the analysis, involving in particular the study of (non-Abelian) gauge-bundles on CY spaces [45] (see however [46]).

An interesting aspect of heterotic string constructions is represented by orbifold models [35]. Here the internal space is given by a six-torus, modded out by a discrete symmetry group (e.g. $T^6/\mathbb{Z}_n$). More recent progress is reported in [47, 48], including in particular the systematic exploration of the phenomenological advantages of so-called 'non-prime' (referring to n) orbifolds. The symmetry breaking to G_{SM} as well as the survival of Higgs doublets without triplet partners is ensured by the appropriate embedding of the discrete orbifold group in $\mathrm{E}_8\times\mathrm{E}_8$. String theory on such spaces, which are locally flat but include singularities, is much more calculable than in the CY case. The orbifold geometries can be viewed as singular limits of CYs.

An even simpler approach to unified models, which includes many of the advantages of full-fledged string constructions, is provided by Orbifold GUTs [37]. These are (mostly) 5d or 6d SUSY field theories with unified gauge group (e.g. $SU(5)$ or $SO(10)$), broken in the process of compactifying to 4d. To give a particularly simple example, consider $SU(5)$ on $\mathbb{R}^{1,3} \times S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$. Here the compact space is an interval of length $\pi R/2$ and the embedding of $\mathbb{Z}_2'$ in the hypercharge direction of $SU(5)$ realizes the breaking to G_{SM}. Concretely, 5d X bosons are given Dirichlet BCs at one endpoint of the interval and thus have no Kaluza-Klein (KK) zero mode. Their lightest modes have mass $\sim 1/R$, making the KK-scale the effective GUT scale. As an implication, the boundary theory has no $SU(5)$ invariance. Nevertheless, since the $SU(5)$-symmetric 5d bulk dominates 4d gauge couplings, unification remains a prediction. Many other features but also problems

[4] The solution of [29] relies on the absence of the fundamental superpotential term $\mu H_u\ H_d$ (or $\mu\, \mathbf{5}_H \overline{\mathbf{5}}_H$). This can be ensured either by a discrete R symmetry or by a $U(1)_R$. The latter clashes with typical superpotentials for the GUT breaking sector. However, higher-dimensional or stringy GUTs, where the triplet Higgs is simply projected out, can be consistent with the $U(1)_R$ symmetry.

[5] All embeddings of G_{SM} in one E_8 factor which are consistent with a breaking-pattern $\mathrm{E}_8 \to SU(5) \to G_{SM}$ are suitable (cf. for example the natural breaking chain from E_8 to G_{SM} through maximal subgroups mentioned at the end of Sect. 93.3). Other embeddings can change the ratios between the three resulting G_{SM} couplings at the GUT scale by group-theoretic factors. Crucially, due to the single 10d gauge coupling, no continuous tuning is possible.

[6] Field-theory thresholds of 4d GUTs are discussed in 93.5.

[7] See however [42].

of 4d GUTs can be circumvented, especially doublet-triplet splitting is easily realized.

With the advent of the string-theory 'flux landscape' [49], which is best understood in 10d type-IIB supergravity, the focus in string model building has shifted to this framework. While type II string theories have no gauge group in 10d, brane-stacks support gauge dynamics. A particularly appealing setting (see e.g. [50]) is provided by type IIB models with D7 branes (defining 8d submanifolds). However, in the $SO(10)$ context the **16** is not available and, for $SU(5)$, the top-Yukawa coupling vanishes at leading order [51]. As a crucial insight, this can be overcome on the non-perturbative branch of type IIB, also known as F-theory [52, 53]. This setting allows for more general branes, thus avoiding constraints of the Dp-brane framework. GUT breaking can be realized using hypercharge flux (the VEV of the $\mathrm{U}(1)_Y$ field strength), an option not available in heterotic models. The whole framework combines the advantages of the heterotic or higher-dimensional unification approach with the more recent progress in understanding moduli stabilization. It thus represents at this moment the most active and promising branch of theory-driven GUT model building (see e.g. [54] and refs. therein).

As a result of the flux-breaking, a characteristic 'type IIB' or 'F-theoretic' tree-level correction to gauge unification arises [55]. The fact that this correction can be rather significant numerically is occasionally held against the framework of F-theory GUTs. However, at a parametric level, this correction nevertheless behaves like a 4d threshold, i.e., it provides $\mathcal{O}(1)$ additive contributions to the inverse 4d gauge couplings $\alpha_i^{-1}(M_G)$.

A final important issue in string GUTs is the so-called string-scale/GUT-scale problem [56]. It arises since, in heterotic compactifications, the Planck scale and the high-scale value of the gauge coupling unambiguously fix the string-scale to about 10^{18} GeV. As the compactification radius R is raised above the string length, the GUT scale (identified with $1/R$) goes down and the string coupling goes up. Within the domain of perturbative string theory, a gap of about a factor ~ 20 remains between the lowest GUT scale achievable in this way and the phenomenological goal of 2×10^{16} GeV. The situation can be improved by venturing into the non-perturbative regime [56], by considering 'anisotropic' geometries with hierarchically different radii R [56, 57] or by including GUT scale threshold corrections [58, 59].

In F-theory GUTs, the situation is dramatically improved since the gauge theory lives only in four out of the six compact dimensions. This allows for models with a 'decoupling limit', where the GUT scale is parametrically below the Planck scale [53]. However, moduli stabilization may not be without problems in such constructions, in part due to a tension between the required large volume and the desirable low SUSY breaking scale.

93.5 Gauge coupling unification

The quantitative unification of the three SM gauge couplings at the energy scale M_G is one of the cornerstones of the GUT paradigm. It is obviously of direct phenomenological relevance. Gauge coupling unification is well understood in the framework of effective field theory (EFT) [60]. In the simplest case, the relevant EFT at energies $\mu \gg M_G$ has a unified gauge symmetry (say $SU(5)$ for definiteness) and a single running gauge coupling $\alpha_G(\mu)$. At energies $\mu \ll M_G$, states with mass $\sim M_G$ (such as X bosons, GUT Higgs, color-triplet Higgs) have to be integrated out. The EFT now has three independent couplings and SM (or SUSY SM) matter content. One-loop renormalization group equations readily allow for an extrapolation to the weak scale,

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(M_G) + \frac{b_i}{2\pi}\log\left(\frac{M_G}{m_Z}\right) + \delta_i\,, \tag{93.3}$$

($i=1,2,3$). Here we defined δ_i to absorb all sub-leading effects, such as threshold corrections at or near the weak scale (e.g. from superpartners and the additional Higgs bosons in the case of the MSSM) and at the GUT scale, and also higher-order corrections. We will discuss them momentarily.

It is apparent from Eq. (93.3) that the three low-scale couplings can be very different. This is due to the large energy range $m_Z \ll \mu \ll M_G$ and the non-universal β-function coefficients ($b_i^{\rm SM} = \{41/10, -19/6, -7\}$ or $b_i^{\rm MSSM} = \{33/5, 1, -3\}$). Incomplete GUT multiplets, such as gauge and Higgs bosons in the SM and also their superpartners and the additional Higgs bosons in the MSSM, contribute to the differences between the β functions. Inverting the argument, one expects that extrapolating the measured couplings to the high scale, we find quantitative unification at $\mu \sim M_G$. While this fails in the SM, it works intriguingly well in the MSSM (cf. Fig. 93.1).

The three equations contained in Eq. (93.3) can be used to determine the three 'unknowns' $\alpha_3(m_Z)$, $\alpha_G(M_G)$ and M_G, assuming that all other parameters entering the equations are given. Focusing on the SUSY case and using the $\overline{\rm MS}$ coupling constants $\alpha_{\rm EM}^{-1}(m_Z)$ and $\sin^2\theta_W(m_Z)$ from [62],

$$\alpha_{\rm EM}^{-1}(m_Z) = 127.955 \pm 0.010\,, \tag{93.4}$$

$$\sin^2\theta_W(m_Z) = 0.23122 \pm 0.00003\,, \tag{93.5}$$

as input, one determines $\alpha_{1,2}^{-1}(m_Z)$, which then gives

$$\alpha_G^{-1}(M_G) \simeq 24.3 \qquad \text{and} \qquad M_G \simeq 2\times 10^{16}\ \text{GeV}\,. \tag{93.6}$$

Here we have set $\delta_i = 0$ for simplicity. Crucially, one in addition obtains a prediction for the low-energy observable α_3,

$$\alpha_3^{-1}(m_Z) = -\frac{5}{7}\alpha_1^{-1}(m_Z) + \frac{12}{7}\alpha_2^{-1}(m_Z) + \Delta_3\,, \tag{93.7}$$

where

$$\Delta_3 = \frac{5}{7}\delta_1 - \frac{12}{7}\delta_2 + \delta_3\,. \tag{93.8}$$

Here we followed the elegant formulation in Ref. [63] of the classical analyses of [7]. Of course, it is a matter of convention which of the three low-energy gauge coupling parameters one 'predicts' and indeed, early works on the subject discussed the prediction of $\sin^2\theta_W$ in terms of $\alpha_{\rm EM}$ and α_3 [64, 65].

Remarkably, the leading order result (i.e. Eq. (93.7) with $\delta_i = 0$) is in excellent agreement with experiments [62]:

$$\alpha_3^{\rm LO}(m_Z) = 0.117 \qquad \text{vs.} \qquad \alpha_3^{\rm EXP}(m_Z) = 0.1181 \pm 0.0011\,. \tag{93.9}$$

However, this near perfection is to some extent accidental. To see this, we now discuss the various contributions to the δ_i (and hence to Δ_3).

The two-loop running correction from the gauge sector $\Delta_3^{(2)}$ and the low-scale threshold correction $\Delta_3^{(l)}$ from superpartners can be summarized as [63]

$$\Delta_3^{(2)} \simeq -0.82 \qquad \text{and} \qquad \Delta_3^{(l)} \simeq \frac{19}{28\pi}\log\left(\frac{m_{\rm SUSY}}{m_Z}\right)\,. \tag{93.10}$$

The relevant scale $m_{\rm SUSY}$ can be estimated as [66]

$$m_{\rm SUSY} \;\to\; m_H^{3/19} m_{\widetilde{H}}^{12/19} m_{\widetilde{W}}^{4/19} \times \left(\frac{m_{\widetilde{W}}}{m_{\widetilde{g}}}\right)^{28/19} \left(\frac{m_{\widetilde{l}}}{m_{\widetilde{q}}}\right)^{3/19}\,, \tag{93.11}$$

where m_H stands for the masses of non-SM Higgs states and superpartner masses are given in self-evident notation. Detailed analyses including the above effects are best done using appropriate software packages, such as SOFTSUSY [61] (or alternatively SuSpect [67] or SPheno [68]). See also [61] for references to the underlying theoretical two-loop analyses.

To get a very rough feeling for these effects, let us assume that all superpartners are degenerate at $m_{\rm SUSY} = 1$ TeV, except for heavier gluinos: $m_{\widetilde{W}}/m_{\widetilde{g}} \simeq 1/3$. This gives $\Delta_3^{(l)} \simeq -0.35 + 0.22\ln(m_{\rm SUSY}/m_Z) \simeq 0.18$. The resulting prediction of $\alpha_3(m_Z) \simeq 0.126$ significantly upsets the perfect one-loop agreement found earlier. Before discussing this issue further, it is useful to introduce yet another important type of correction, the high or GUT scale thresholds.

To discuss high scale thresholds, let us set all other corrections to zero for the moment and write down a version of Eq. (93.3)

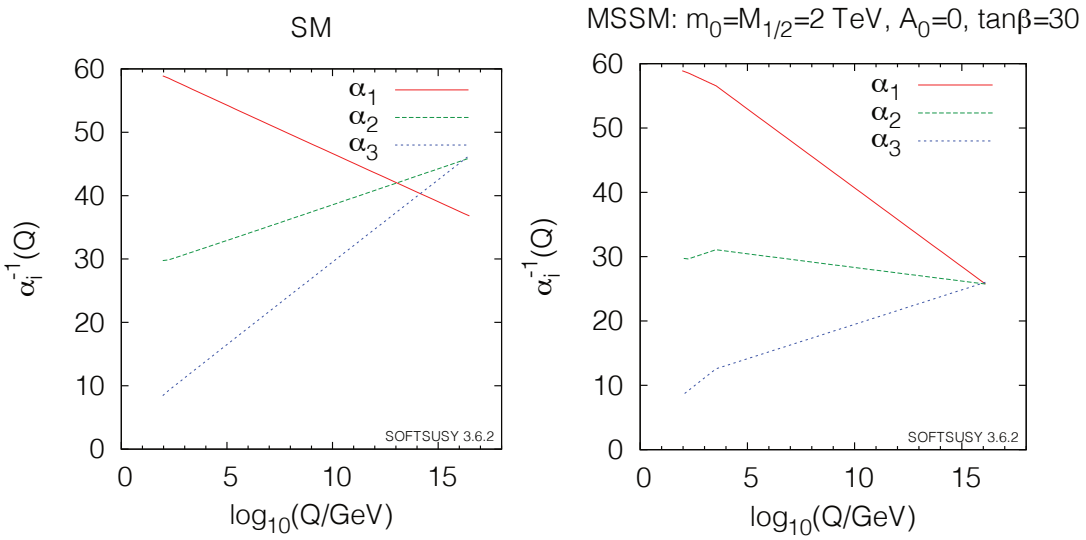

Figure 93.1: Running couplings in SM and MSSM using two-loop RG evolution. The SUSY threshold at 2 TeV is clearly visible on the MSSM side. (We thank Ben Allanach for providing the plots created using SOFTSUSY [61].)

that captures the running near and above the GUT scale more correctly. The threshold correction at one-loop level can be evaluated accurately by the simple step-function approximation for the β functions in the $\overline{\rm DR}$ scheme[8] [72],

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(\mu) + \frac{1}{2\pi}\left[b_i \ln\frac{\mu}{m_Z} + b_i^C \ln\frac{\mu}{M_C} + b_i^X \ln\frac{\mu}{M_X} + b_i^\Phi \ln\frac{\mu}{M_\Phi}\right] . \quad (93.12)$$

Here we started the running at some scale $\mu \gg M_G$, including the contribution of the minimal set of states relevant for the transition from the high-scale $SU(5)$ model to the MSSM. These are the color-triplet Higgs multiplets with mass M_C, massive vector multiplets of X-bosons with mass M_X (including GUT Higgs degrees of freedom), and the remaining GUT-Higgs fields and superpartners with mass M_Φ. The coefficients $b_i^{C,X,\Phi}$ can be found in Ref. [73]. Crucially, the b_i in Eq. (93.12) conspire to make the running GUT-universal at high scales, such that the resulting prediction for α_3 does not depend on the value of μ.

To relate this to our previous discussion, we can, for example, define $M_G \equiv M_X$ and then choose $\mu = M_G$ in Eq. (93.12). This gives the high-scale threshold corrections

$$\delta_i^{(h)} = \frac{1}{2\pi}\left[b_i^C \ln\frac{M_G}{M_C} + b_i^\Phi \ln\frac{M_G}{M_\Phi}\right] , \quad (93.13)$$

and a corresponding correction $\Delta_3^{(h)}$. To get some intuition for the magnitude, one can furthermore assume $M_\Phi = M_G$, finding (with $b_i^C = \{2/5, 0, 1\}$)

$$\Delta_3^{(h)} = \frac{9}{14\pi}\ln\left(\frac{M_G}{M_C}\right) . \quad (93.14)$$

To obtain the desired effect of $-\Delta_3^{(2)} - \Delta_3^{(l)} \simeq +0.64$, the triplet Higgs would have to be by about a factor 20 lighter than the GUT scale. While this is ruled out by nucleon decay in the minimal model [74] as will be discussed Sec. 93.6, it is also clear that threshold corrections of this order of magnitude can, in general, be realized with a certain amount of GUT-scale model building, e.g. in specific $SU(5)$ [25] or $SO(10)$ [26,27] constructions. Corrections can also be much larger or of different sign if, as is required in many fully realistic 4d GUT models, many additional (and in particular higher) representations are introduced. Thus, there is considerable model building freedom. Nevertheless, a significant constraint from getting the right GUT threshold corrections while keeping the triplet Higgs heavy remains.

The above analysis implicitly assumes universal soft SUSY breaking masses at the GUT scale, which directly affect the spectrum of SUSY particles at the weak scale. In the simplest case we have a universal gaugino mass $M_{1/2}$, a universal mass for squarks and sleptons m_{16} and a universal Higgs mass m_{10}, as motivated by $SO(10)$. In some cases, threshold corrections to gauge coupling unification can be exchanged for threshold corrections to soft SUSY parameters (see [75] and refs. therein). For example, if gaugino masses were not unified at M_G and, in particular, gluinos were lighter than winos at the weak scale (cf. Eq. (93.11)), then it is possible that, due to weak scale threshold corrections, a much smaller or even slightly negative threshold correction at the GUT scale would be consistent with gauge coupling unification [76].

It is also noteworthy that perfect unification can be realized without significant GUT-scale corrections, simply by slightly raising the (universal) SUSY breaking scale. In this case the dark matter abundance produced by thermal processes in the early Universe (if the lightest neutralino is the dark matter particle) is too high. However, even if the gaugino mass in the MSSM is about 1 TeV to explain the dark matter abundance, if the Higgsino and the non-SM Higgs boson masses are about 10-100 TeV, the effective SUSY scale can be raised [77]. This setup is realized in split SUSY [78] or the pure gravity mediation model [79] based on anomaly mediation [80]. Since the squarks and sleptons are much heavier than the gaugino masses in those setups, a gauge hierarchy problem is reintroduced. The facts that no superpartners have so far been seen at the LHC and that the observed Higgs mass favors heavier stop masses than about 1 TeV force one to accept a certain amount of fine-tuning anyway.

For non-SUSY GUTs or GUTs with a very high SUSY breaking scale to fit the data, new light states in incomplete GUT multiplets or multiple GUT breaking scales are required. For example, non-SUSY models $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R \to$ SM, with the second breaking scale of order an intermediate scale, determined by light neutrino masses using the see-saw mechanism, can fit the low-energy data for gauge couplings [81] and at the same time survive nucleon decay bounds [82]. Alternatively, one can appeal to string-theoretic corrections discussed in Sec. 93.4 to compensate for a high SUSY breaking scale. This has, for example, been concretely analyzed in the context of F-theory GUTs in [83]. Similarly, one may even wonder whether particularly large GUT threshold corrections could be sufficient to ensure non-SUSY precision unification. Notice here that the gauge coupling unifica-

[8] The $\overline{\rm DR}$ scheme is frequently used in a supersymmetric regularization [69]. The renormalization transformation of the gauge coupling constants from $\overline{\rm MS}$ to $\overline{\rm DR}$ scheme is given in Ref. [70]. For an alternative treatment using holomorphic gauge couplings and NSVZ β-functions see e.g. [71].

tion predicts just one parameter. When introducing new states, typically one can fit the data by choice of their masses. This is not the case in SUSY GUTs with low-scale SUSY breaking scale where the masses are constrained by fine-tuning.

In 5d or 6d orbifold GUTs, certain "GUT scale" threshold corrections come from the Kaluza-Klein modes between the compactification scale, $M_c \sim 1/R$, and the effective cutoff scale M_*. In string theory, this cutoff scale is the string scale. Gauge coupling unification at two loops then constrains the values of M_c and M_*.[9] Often, one finds M_c to be lower than the 4d GUT scale. Since the X-bosons, responsible for nucleon decay, get mass at the compactification scale, this has significant consequences for nucleon decay.

Finally, it has been shown that non-supersymmetric GUTs in warped 5d orbifolds can be consistent with gauge coupling unification. This assumes (in 4d language) that the r.h. top quark and the Higgs doublets are composite-like objects with a compositeness scale in the TeV range [85].

93.6 Nucleon decay

Quarks and leptons are indistinguishable in any 4d GUT, and both the baryon (B) and lepton number (L) are not conserved. This leads to baryon-number-violating nucleon decay. In addition to baryon-number violation, lepton-number violation is also required for nucleon decay since, in the SM, leptons are the only free fermions which are lighter than nucleons. The lowest-dimension operators relevant for nucleon decay are (B+L) violating dimension-six four-fermion-terms in the SM, and all baryon-violating operators with dimension less than seven preserve (B–L) [1, 86].

In $SU(5)$ GUTs, the dimension-six operators are induced by X boson exchange. These operators are suppressed by $(1/M_X^2)$ (M_X is the X boson mass), and the nucleon lifetime is given by $\tau_N \propto M_X^4/(\alpha_G^2\, m_p^5)$ (m_p is proton mass). The dominant decay mode of the proton (and the baryon-violating decay mode of the neutron), via X boson exchange, is $p \to e^+\, \pi^0$ ($n \to e^+\, \pi^-$). In any simple gauge symmetry, with one universal GUT coupling α_G and scale M_X, the nucleon lifetime from gauge boson exchange is calculable. Hence, the GUT scale may be directly observed via the extremely rare decay of the nucleon. Experimental searches for nucleon decay began with the Kolar Gold Mine, Homestake, Soudan, NUSEX, Frejus, HPW, IMB, and Kamiokande detectors [64]. The present experimental bounds on the modes come from Super-Kamiokande. With 306 kton-years of data they find $\tau_p/\mathrm{Br}(p \to e^+\pi^0) > 1.67 \times 10^{34}$ years at 90% CL [87]. In addition, Hyper-Kamiokande [88] is planned to reach to $\tau_p/\mathrm{Br}(p \to e^+\pi^0) \sim 10^{35}$ years. The hadronic matrix elements for baryon-number-violating operators are evaluated with lattice QCD simulations [89]. In SUSY $SU(5)$ GUTs, the lower bound on the X boson mass from null results in nucleon decay searches is approaching 10^{16} GeV [90], which is close to the GUT scale suggested by gauge coupling unification. On the other hand, the prediction for nucleon decay in non-SUSY GUTs is hard to quantify. The reason is that gauge couplings do not unify with just the SM particle content. Once extra states or large thresholds are included to ensure precision unification, a certain range of unification scales is allowed.

In SUSY GUTs there are additional sources for baryon and/or lepton-number violation – dimension-four and five operators [14]. These arise since, in the SUSY SM, quarks and leptons have scalar partners (squarks and sleptons). Although our notation does not change, when discussing SUSY models our fields are chiral superfields and both fermionic and bosonic matter is implicitly represented by those. In this language, baryon- and/or lepton-number-violating dimension-four and five operators are given as so-called F terms of products of chiral superfields, which contain two fermionic components and the rest scalars or products of scalars. Within the context of $SU(5)$ the dimension-four and five operators have the form

$$(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}) \supset (u^c\ d^c\ d^c) + (Q\ L\ d^c) + (e^c\ L\ L),$$

$$(\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \bar{\mathbf{5}}) \supset (Q\ Q\ Q\ L) + (u^c\ u^c\ d^c\ e^c) + B\text{- and } L\text{-conserving terms},$$

respectively.

The dimension-four operators in $(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}})$ violate either baryon number or lepton number. The nucleon lifetime is extremely short if both types of dimension-four operators are present in the SUSY SM since squark or slepton exchange induces the dangerous dimension-six SM operators. Even in the case that they violate baryon number or lepton number only but not both, they are constrained by various phenomena [91]. For example, the primordial baryon number in the Universe is washed out unless the dimensionless coupling constants are less than 10^{-7}. Both types of operators can be eliminated by requiring R parity, which distinguishes Higgs from ordinary matter multiplets. R parity [92] or its cousin, matter parity [6, 93], act as $F \to -F$, $H \to H$ with $F = \{\mathbf{10}, \bar{\mathbf{5}}\}$, $H = \{\bar{\mathbf{5}}_H, \mathbf{5}_H\}$ in $SU(5)$.[10] In $SU(5)$, the Higgs multiplet $\bar{\mathbf{5}}_H$ and the matter multiplets $\bar{\mathbf{5}}$ have identical gauge quantum numbers. In E_6, Higgs and matter multiplets could be unified within the fundamental **27** representation. Only in $SO(10)$ are Higgs and matter multiplets distinguished by their gauge quantum numbers. The Z_4 center of $SO(10)$ distinguishes **10**s from **16**s and can be associated with R parity [94].

The baryon-number violating dimension-five operators have a dimensionful coupling. They are generated by integrating out the color-triplet Higgs with GUT-scale mass in SUSY GUTs such that the coefficient is suppressed by $1/M_G$. Note that both triplet Higgsinos (due to their fermionic nature) and Higgs scalars (due to their mass-enhanced trilinear coupling with matter) contribute to the operators. The dimension-five operators include squarks and/or sleptons. To allow for nucleon decay, these must be converted to light quarks or leptons by exchange of a gaugino or Higgsino in the SUSY SM. The nucleon lifetime is proportional to $M_G^2\, m_{\mathrm{SUSY}}^2/m_p^5$, where m_{SUSY} is the SUSY breaking scale. Thus, dimension-five operators may predict a shorter nucleon lifetime than dimension-six operators. Unless accidental cancellations are present, the dominant decay modes from dimension-five operators include a K meson, such as $p \to K^+\, \bar{\nu}$ ($n \to K^0\, \bar{\nu}$). This is due to a simple symmetry argument: The operators are given as $(Q_i\ Q_j\ Q_k\ L_l)$ and $(u_i^c\ u_j^c\ d_k^c\ e_l^c)$, where $i, j, k, l\,(= 1, 2, 3)$ are family indices and color and weak indices are implicit. They must be invariant under $SU(3)_C$ and $SU(2)_L$ so that their color and weak doublet indices must be anti-symmetrized. Since these operators are given by bosonic superfields, they must be totally symmetric under interchange of all indices. Thus, the first operator vanishes for $i = j = k$ and the second vanishes for $i = j$. Hence a second or third generation member exists in the dominant modes of nucleon decay unless these modes are accidentally suppressed [93].

The Super-Kamiokande bounds on the proton lifetime severely constrain the dimension-five operators. With 306 kton-years of data they find $\tau_p/\mathrm{Br}(p \to K^+\bar{\nu}) > 6.61 \times 10^{33}$ years at 90% CL [87]. In the minimal SUSY $SU(5)$, $\tau_p/\mathrm{Br}(p \to K^+\bar{\nu})$ is smaller than about 10^{31} years if the triplet Higgs mass is 10^{16} GeV and $m_{\mathrm{SUSY}} = 1$ TeV [95]. The triplet Higgs mass bound from nucleon decay is then in conflict with gauge coupling unification so that this model is considered to be ruled out [74].

Since nucleon decay induced by the triplet Higgs is a severe problem in SUSY GUTs, various proposals for its suppression have been made. First, some accidental symmetry or accidental structure in non-minimal Higgs sectors in $SU(5)$ or $SO(10)$ theories may suppress the dimension-five operators [22, 26, 27, 96]. Symmetries to suppress the dimension-five operators are typically broken by the VEVs responsible for the color-triplet Higgs masses. Consequently, the dimension-five operators are generically generated via the triplet Higgs exchange in SUSY $SU(5)$ GUTs, as mentioned above. In other words, the nucleon decay is suppressed if the Higgs triplets in $\bar{\mathbf{5}}_H$ and $\mathbf{5}_H$ do not have a common mass term but, instead, their mass terms involve partners

[9] It is interesting to note that a ratio $M_*/M_c \sim 100$, needed for gauge coupling unification to work in orbifold GUTs, is typically the maximum value for this ratio consistent with perturbativity [84].

[10] This forbids the dimension-four operator $(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}})$, but allows the Yukawa couplings for quark and lepton masses of the form $(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}_H)$ and $(\mathbf{10}\ \mathbf{10}\ \mathbf{5}_H)$. It also forbids the dimension-three, lepton-number-violating operator $(\bar{\mathbf{5}}\ \mathbf{5}_H) \supset (L\ H_u)$ as well as the dimension-five, baryon-number-violating operator $(\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \bar{\mathbf{5}}_H) \supset (Q\ Q\ Q\ H_d) + \cdots$.

from other $SU(5)$ multiplets. Second, the SUSY breaking scale may be around $\mathcal{O}$(10–100) TeV in order to explain the observed Higgs boson mass at the LHC. In this case, nucleon decay is automatically suppressed [78,97,98]. Third, accidental cancellations among diagrams due to a fine-tuned structure of squark and slepton flavor mixing might suppress nucleon decay [99]. Last, we have also implicitly assumed a hierarchical structure for Yukawa matrices in the analysis. It is however possible to fine-tune a hierarchical structure for quarks and leptons which baffles the family structure so that the nucleon decay is suppressed [100]. The upper bound on the proton lifetime from some of these theories is approximately a factor of 10 above the experimental bounds. Future experiments with larger neutrino detectors, such as JUNO [101], Hyper-Kamiokande [88] and DUNE [102], are planned and will have higher sensitivities to nucleon decay.

Are there ways to avoid the stringent predictions for proton decay discussed above? Orbifold GUTs and string theories, see Sec. 93.4, contain grand unified symmetries realized in higher dimensions. In the process of compactification and GUT symmetry breaking, the triplet Higgs states may be removed (projected out of the massless sector of the theory). In such models, the nucleon decay due to dimension-five operators can be severely suppressed or eliminated completely. However, nucleon decay due to dimension-six operators may be enhanced, since the gauge-bosons mediating proton decay obtain mass at the compactification scale, M_c, which is typically less than the 4d GUT scale (cf. Sec. 93.5). Alternatively, the same projections which eliminate the triplet Higgs may rearrange the quark and lepton states such that the massless states of one family come from different higher-dimensional GUT multiplets. This can suppress or completely eliminate even dimension-six proton decay. Thus, enhancement or suppression of dimension-six proton decay is model-dependent. In some complete 5d orbifold GUT models [63, 103] the lifetime for the decay $\tau_p/\mathrm{Br}(p \to e^+\pi^0)$ can be near the bound of 1×10^{34} years with, however, large model-dependence and/or theoretical uncertainties. In other cases, the modes $p \to K^+\bar{\nu}$ and $p \to K^0\mu^+$ may be dominant [63]. Thus, interestingly, the observation of nucleon decay may distinguish string or higher-dimensional GUTs from 4d ones.

In orbifold GUTs or string theory, new discrete symmetries consistent with SUSY GUTs can forbid all dimension-three and four baryon- and lepton-number-violating operators. Even the μ term and dimension-five baryon- and lepton-number-violating operators can be forbidden to all orders in perturbation theory [33]. The μ term and dimension-five baryon- and lepton-number-violating operators may then be generated, albeit sufficiently suppressed, via non-perturbative effects. The simplest example of this is a Z_4^R symmetry which is the unique discrete R symmetry consistent with $SO(10)$ [33]. Even though it forbids the dimension-five proton decay operator to the desired level, it allows the required dimension-five neutrino mass term. In this case, proton decay is dominated by dimension-six operators, leading to decays such as $p \to e^+\pi^0$.

93.7 Yukawa coupling unification

In the SM, masses and mixings for quarks and leptons come from the Yukawa couplings with the Higgs doublet, but the values of these couplings remain a mystery. GUTs provide at least a partial understanding since each generation is embedded in unified multiplet(s). Specifically, since quarks and leptons are two sides of the same coin, the GUT symmetry relates the Yukawa couplings (and hence the masses) of quarks and leptons.

In $SU(5)$, there are two types of independent renormalizable Yukawa interactions given by λ_{ij} $(\mathbf{10}_i\ \mathbf{10}_j\ \mathbf{5}_H)$ + λ'_{ij} $(\mathbf{10}_i\ \bar{\mathbf{5}}_j\ \bar{\mathbf{5}}_H)$. These contain the SM interactions $\lambda_{ij}\ (Q_i\ u^c_j\ H_u) + \lambda'_{ij}\ (Q_i\ d^c_j\ H_d + e^c_i\ L_j\ H_d)$. Here $i, j\ (=1,2,3)$ are, as before, family indices. Hence, at the GUT scale we have tree-level relations between Yukawa coupling constants for charged lepton and down quark masses, such as $\lambda_b = \lambda_\tau$ in which $\lambda_{b/\tau}$ are the bottom quark /τ lepton Yukawa coupling constants [104,105]. In $SO(10)$, there is only one type of independent renormalizable Yukawa interaction given by λ_{ij} $(\mathbf{16}_i\ \mathbf{16}_j\ \mathbf{10}_H)$, leading to relations among all Yukawa coupling constants and quark and lepton masses within one generation [106,107] (such as $\lambda_t = \lambda_b = \lambda_\tau$, with λ_t the top quark Yukawa coupling constant).

In addition to gauge coupling unification, the ratio of bottom quark and τ lepton mass has been a central target in the study of GUTs since it was found that this ratio was almost consistent with observations after including the QCD correction [104]. Today the quark masses and the gauge coupling constants are known precisely such that, as discussed below, the ratio of bottom quark and τ lepton mass has become a target of precision analyses in the GUT context.

93.7.1 *The third generation, b–τ or t–b–τ unification*

Third generation Yukawa couplings are larger than those of the first two generations. Hence, the fermion mass relations predicted from renormalizable GUT interactions which we introduced above are expected to be more reliable. In order to compare them with data, we have to include the radiative correction to these relations from the RG evolution between GUT and fermion mass scale, from integrating out heavy particles at the GUT scale, and from weak scale thresholds.

Since testing Yukawa coupling unification is only possible in models with successful gauge coupling unification, we here focus on SUSY GUTs. In the MSSM, top and bottom quark and τ lepton masses are related to the Yukawa coupling constants at the scale m_Z as

$$m_t(m_Z) = \lambda_t(m_Z)\, v_u(1+\delta m_t/m_t),$$
$$m_{b/\tau}(m_Z) = \lambda_{b/\tau}(m_Z)\, v_d(1+\delta m_{b/\tau}/m_{b/\tau}),$$

where $\langle H_u^0\rangle \equiv v_u = \sin\beta\ v/\sqrt{2}$, $\langle H_d^0\rangle \equiv v_d = \cos\beta\ v/\sqrt{2}$, $v_u/v_d \equiv \tan\beta$ and $v \sim 246$ GeV is fixed by the Fermi constant, G_μ. Here, $\delta m_f/m_f$ $(f = t, b, \tau)$ represents the threshold correction due to integrating out SUSY partners. For the bottom quark mass, it is found [108] that the dominant corrections come from the gluino-sbottom and from the Higgsino-stop loops,

$$\left(\frac{\delta m_b}{m_b}\right)_{g_3} \sim \frac{g_3^2}{6\pi^2}\frac{m_{\tilde{g}}\mu}{m^2_{\mathrm{SUSY}}}\tan\beta \qquad \text{and}$$
$$\left(\frac{\delta m_b}{m_b}\right)_{\lambda_t} \sim \frac{\lambda_t^2}{16\pi^2}\frac{A_t\mu}{m^2_{\mathrm{SUSY}}}\tan\beta\,, \tag{93.16}$$

where $m_{\tilde{g}}$, μ, and A_t stand for gluino and Higgsino masses and trilinear stop coupling, respectively. Note that Eq. (93.16) only illustrates the structure of the corrections – non-trivial functional dependences on several soft parameters $\sim m_{\mathrm{SUSY}}$ have been suppressed. For the full one-loop correction to the bottom quark mass see, for example, Ref. [109].

Note also that the corrections do not go to zero as SUSY particles become much heavier than m_Z. They may change the bottom quark mass at the $\mathcal{O}(10)$% level for $\tan\beta = \mathcal{O}(10)$. The total effect is sensitive to the relative phase between gluino and Higgsino masses since $A_t \sim -m_{\tilde{g}}$ due to the infrared fixed point nature of the RG equation for A_t [110] in settings where SUSY breaking terms come from Planck scale dynamics, such as gravity mediation. The τ lepton mass also receives a similar correction, though only at the few % level. The top quark mass correction, not being proportional to $\tan\beta$, is at most 10% [111].

Including one loop threshold corrections at m_Z and additional RG running, one finds the top, bottom and τ pole masses. In SUSY GUTs, b–τ unification has two possible solutions with $\tan\beta \sim 1$ or $\mathcal{O}(10)$. The small $\tan\beta$ solution may be realized in the MSSM if superpartner masses are $\mathcal{O}(10)$ TeV, as suggested by the observed Higgs mass [97]. The large $\tan\beta$ limit such as $\tan\beta \sim 40$–50 overlaps the $SO(10)$ symmetry relation [111, 112]. When $\tan\beta$ is large, there are significant threshold corrections to down quark masses as mentioned above, and Yukawa unification is only consistent with low-energy data in a restricted region of SUSY parameter space, with important consequences for SUSY searches [111, 113]. More recent analyses of Yukawa unification after LHC Run-I are found in Ref. [114].

Gauge coupling unification is also successful in the scenario of split supersymmetry [78], in which squarks and sleptons have mass

at a scale $\tilde{m} \gg m_Z$, while gauginos and/or Higgsinos have masses of order the weak scale. Unification of b–τ Yukawa couplings requires $\tan\beta$ to be fine-tuned close to 1 [97]. If by contrast, $\tan\beta \gtrsim 1.5$, b–τ Yukawa unification only works for $\tilde{m} \lesssim 10^4$ GeV. This is because the effective theory between the gaugino mass scale and $\tilde{m}$ includes only one Higgs doublet, as in the standard model. As a result, the large top quark Yukawa coupling tends to increase the ratio λ_b/λ_τ due to the vertex correction, which is absent in supersymmetric theories, as one runs down in energy below $\tilde{m}$. This is opposite to what happens in the MSSM where the large top quark Yukawa coupling lowers the ratio λ_b/λ_τ [105].

93.7.2 *Beyond leading order: three-family models*

Simple Yukawa unification is not possible for the first two generations. Indeed, the simplest implementation of $SU(5)$ implies $\lambda_s = \lambda_\mu$, $\lambda_d = \lambda_e$ and hence $\lambda_s/\lambda_d = \lambda_\mu/\lambda_e$. This is an RG-invariant relation which extrapolates to $m_s/m_d = m_\mu/m_e$ at the weak scale, in serious disagreement with data ($m_s/m_d \sim 20$ and $m_\mu/m_e \sim 200$). An elegant solution to this problem was given by Georgi and Jarlskog [115] (for a recent analysis in the SUSY context see [116]).

More generally, we have to recall that in all of the previous discussion of Yukawa couplings, we assumed renormalizable interactions as well as the minimal matter and Higgs content. Since the GUT scale is close to the Planck scale, higher-dimension operators involving the GUT-breaking Higgs may modify the predictions, especially for lower generations. An example is provided by the operators $\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}_H\ \mathbf{24}_H$ with $\mathbf{24}_H$ the GUT-breaking Higgs of $SU(5)$. We can fit parameters to the observed fermion masses with these operators, though some fine-tuning is introduced in doing so. The SM Higgs doublet may come in part from higher representations of the GUT group. For example, the **45** of $SU(5)$ includes an $SU(2)_L$ doublet with appropriate $U(1)_Y$ charge [115]. This **45** can, in turn, come from the **120** or **126** of $SO(10)$ after its breaking to $SU(5)$ [117, 118]. These fields may also have renormalizable couplings with quarks and leptons. The relations among the Yukawa coupling constants in the SM are modified if the SM Higgs doublet is a linear combination of several such doublets from different $SU(5)$ multiplets. Finally, the SM fermions may not be embedded in GUT multiplets in the minimal way. Indeed, if all quarks and leptons are embedded in **16**s of $SO(10)$, the renormalizable interactions with $\mathbf{10}_H$ cannot explain the observed CKM mixing angles. This situation improves when extra matter multiplets, such as **10**, are introduced: After $U(1)_X$, which distinguishes the $\bar{\mathbf{5}}$s coming from the **16** and the **10** of $SO(10)$, is broken (e.g. by a VEV of $\mathbf{16}_H$ or $\mathbf{126}_H$), the r.h. down quarks and l.h. leptons in the SM can be linear combinations of components in **16**s and **10**s. As a result, $\lambda \neq \lambda'$ in $SU(5)$ [119].

To construct realistic three-family models, some or all of the above effects can be used. Even so, to achieve significant predictions for fermion masses and mixing angles grand unification alone is not sufficient. Other ingredients, for example additional global family symmetries are needed (in particular, non-Abelian symmetries can strongly reduce the number of free parameters). These family symmetries constrain the set of effective higher-dimensional fermion mass operators discussed above. In addition, sequential breaking of the family symmetry can be correlated with the hierarchy of fermion masses [120]. One simple, widely known idea in this context is to ensure that each $\mathbf{10}_i$ enters Yukawa interactions together with a suppression factor ϵ^{3-i} (ϵ being a small parameter). This way one automatically generates a stronger hierarchy in up-type quark Yukawas as compared to down-type quark and lepton Yukawas and no hierarchy for neutrinos, which agrees with observations at the $\mathcal{O}(1)$-level. Three-family models exist which fit all the data, including neutrino masses and mixing [27, 121].

Finally, a particularly ambitious variant of unification is to require that the fermions of all three generations come from a single representation of a large gauge group. A somewhat weaker assumption is that the flavor group (e.g. $SU(3)$) unifies with the SM gauge group in a simple gauge group at some energy scale $M \geq M_G$. Early work on such 'flavor-unified GUTs', see e.g. [119, 122], has been reviewed in [123, 124]. For a selection of more recent papers see [125]. In such settings, Yukawa couplings are generally determined by gauge couplings together with symmetry breaking VEVs. This is reminiscent of heterotic string GUTs, where all couplings come from the 10d gauge coupling. However, while the $E_8 \to SU(3)\times E_6$ branching rule $\mathbf{248} = (\mathbf{8},\mathbf{1}) + (\mathbf{1},\mathbf{78}) + (\mathbf{3},\mathbf{27}) + (\overline{\mathbf{3}},\overline{\mathbf{27}})$ looks very suggestive in this context, the way in which most modern heterotic models arrive at three generations is actually more complicated.

93.8 Neutrino masses

We see from atmospheric and solar neutrino oscillation observations, along with long baseline accelerator and reactor experiments, that neutrinos have finite masses. By adding three "sterile" neutrinos ν_i^c with Yukawa couplings $\lambda_{\nu,ij}\ (\nu_i^c\ L_j\ H_u)$ $(i,j = 1,2,3)$, one easily obtains three massive Dirac neutrinos with mass $m_\nu = \lambda_\nu\ v_u$, analogously to quark and charged lepton masses. However, in order to obtain a τ neutrino with mass of order 0.1 eV, one requires the exceedingly small coupling ratio $\lambda_{\nu_\tau}/\lambda_\tau \lesssim 10^{-10}$. By contrast, in GUTs the seesaw mechanism *naturally* explains such tiny neutrino masses as follows [2–4]: The sterile neutrinos have no SM gauge quantum numbers so that there is no symmetry other than global lepton number which forbids the Majorana mass term $\frac{1}{2}M_{ij}\ \nu_i^c\ \nu_j^c$. Note also that sterile neutrinos can be identified with the r.h. neutrinos necessarily contained in complete families of $SO(10)$ or Pati-Salam models. Since the Majorana mass term violates $U(1)_X$ in $SO(10)$, one might expect $M_{ij} \sim M_G$. The heavy sterile neutrinos can be integrated out, defining an effective low-energy theory with only three light active Majorana neutrinos with the effective dimension-five operator

$$-\mathcal{L}_{eff} = \frac{1}{2}c_{ij}\ (L_i\ H_u)\ (L_j\ H_u)\,, \tag{93.17}$$

where $c = \lambda_\nu^T\ M^{-1}\ \lambda_\nu$. This then leads to a 3×3 Majorana neutrino mass matrix $m = m_\nu^T\ M^{-1}\ m_\nu$.

The seesaw mechanism implemented by r.h. neutrinos is sometimes called the type-I seesaw model. There are variant models in which the dimension-five operator for neutrino masses is induced in different ways: In the type-II model, an $SU(2)_L$ triplet Higgs boson Σ is introduced to have couplings ΣL^2 and also ΣH_u^2 [117, 126]. In the type-III model, an $SU(2)_L$ triplet of fermions $\tilde{\Sigma}$ with a Yukawa coupling $\tilde{\Sigma}LH_u$ is introduced [127]. In these models, the dimension-five operator is induced by integrating out the triplet Higgs boson or fermions. Such models can also be implemented in GUTs by introducing Higgs bosons in the **15** or fermions in the **24** in $SU(5)$ GUTs or the **126** in $SO(10)$ GUTs. Notice that the gauge non-singlet fields in the type-II and III models have masses at the intermediate scale. Thus, gauge coupling unification is not automatic if these variant mechanisms are implemented in SUSY GUTs.

Atmospheric neutrino oscillations discovered by Super-Kamiokande [128] require neutrino masses with $\Delta m_\nu^2 \sim 2.5\times 10^{-3}$ eV^2 with maximal mixing [62], in the simplest scenario of two neutrino dominance. With hierarchical neutrino masses this implies $m_{\nu_\tau} = \sqrt{\Delta m_\nu^2} \sim 0.05$ eV. Next, we can try to relate the neutrino Yukawa coupling to the top quark Yukawa coupling, $\lambda_{\nu_\tau} = \lambda_t$ at the GUT scale, as in $SO(10)$ or $SU(4)\times SU(2)_L \times SU(2)_R$ models. This gives $M \sim 10^{14}$ GeV, which is remarkably close to the GUT scale.

Neutrinos pose a special problem for GUTs. The question is why the quark mixing angles in the CKM matrix are small while there are two large lepton mixing angles in the PMNS matrix. Global fits of neutrino masses and mixing angles can, for example, be found in Refs. [129] and [130]. For SUSY GUT models which fit quark and lepton masses, see Ref. [131] for reviews. Finally, for a compilation of the range of SUSY GUT predictions for neutrino mixing, see [132].

93.9 Selected topics

93.9.1 *Global symmetries*

As we discussed, global symmetries are frequently introduced to control higher-dimension operators in GUT models. This is particularly important in the context of nucleon decay but also plays a role in GUT-based flavor model building and cosmological applications, such as baryogenesis and inflation. However,

we should note that appealing to global symmetries to suppress specific interactions may not be as straightforward as it naively seems. Indeed, there are two possibilities: On the one hand, the relevant symmetry might be gauged at a higher scale. Effects of the VEVs responsible for the spontaneous breaking are then in principle dangerous and need to be quantified. On the other hand, the symmetry might be truly only global. This must e.g. be the case for anomalous symmetries, which are then also violated by field-theoretic non-perturbative effects. The latter can in principle be exponentially small. It is, however, widely believed that global symmetries are always broken in quantum gravity (see e.g. [133]). One then needs to understand which power or functional form the Planck scale suppression of the relevant interaction has. For example, dimension-five baryon number violating operators suppressed by just one unit of the Planck or string scale are completely excluded.

In view of the above, it is also useful to recall that in string models 4d global symmetries generally originate in higher-dimensional gauge symmetries [38, 134]. Here 'global' implies that the gauge boson has acquired a Stückelberg-mass. This is a necessity in the anomalous case (Green-Schwarz mechanism [135]) but can also happen to non-anomalous symmetries. One expects no symmetry violation beyond the well-understood non-perturbative effects. Discrete symmetries arise as subgroups of continuous gauge symmetries, such as $\mathbb{Z}_N \subset U(1)$. In particular, non-anomalous subgroups of Stückelberg-massive $U(1)$s represent unbroken discrete gauge symmetries and as such are non-perturbatively exact (see e.g. [136]). Of course, such discrete gauge symmetries may also arise as remnants of continuous gauge symmetries after conventional 4d spontaneous breaking.

93.9.2 *Anomaly constraints vs. GUT paradigm*

As emphasized at the very beginning, the fact that the SM fermions of one generation fill out the $\mathbf{10}+\overline{\mathbf{5}}$ of $SU(5)$ appears to provide overwhelming evidence for some form of GUT embedding. However, one should be aware that a counterargument can be made which is related to the issue of 'charge quantization by anomaly cancellation' (see [137,138] for some early papers and [139] for a more detailed reference list): Imagine we only knew that the low-energy gauge group were G_{SM} and the matter content included the $(\mathbf{3},\mathbf{2})_Y$, i.e. a 'quark doublet' with $U(1)$-charge Y. One can then ask which possibilities exist of adding further matter to ensure the cancellation of all triangle anomalies. It turns out that this problem has only three different, minimal[11] solutions [138]. One of those is precisely a single SM generation, with the apparent '$SU(5)$-ness' emerging accidentally. Thus, if one randomly picks models from the set of consistent gauge theories, preconditioning on G_{SM} and $(\mathbf{3},\mathbf{2})_Y$, one may easily end up with '$\mathbf{10}+\overline{\mathbf{5}}$' of an $SU(5)$ that is in no way dynamically present. This is precisely what happens in the context of non-GUT string model building [140].

93.9.3 *Magnetic monopoles*

In the broken phase of a GUT there are typically localized classical solutions carrying magnetic charge under an unbroken $U(1)$ symmetry [141]. These magnetic monopoles with mass of order M_G/α_G can be produced during a possible GUT phase transition in the early Universe. The flux of magnetic monopoles is experimentally found to be less than $\sim 10^{-16}$ cm^{-2} s^{-1} sr^{-1} [142]. Many more are however predicted, hence the GUT monopole problem. In fact, one of the original motivations for inflation was to solve the monopole problem by exponential expansion after the GUT phase transition [143] and hence dilution of the monopole density. Other possible solutions to the monopole problem include: sweeping them away by domain walls [144], $U(1)$ electromagnetic symmetry breaking at high temperature [145] or GUT symmetry non-restoration [146]. Parenthetically, it was also shown that GUT monopoles can catalyze nucleon decay [147]. A significantly stronger bound on the monopole flux can then be obtained by considering X-ray emission from radio pulsars due to monopole capture and the subsequent nucleon decay catalysis [148].

Note that the present upper bound on the inflationary vacuum energy density is very close to the GUT scale, $V_{inf}^{1/4} = (1.88\times10^{16}\,\mathrm{GeV})\times(r/0.10)^{1/4}$, with the scalar-to-tensor ratio constrained to $r<0.07$ [149]. This guarantees that reheating does not lead to temperatures above M_G and hence the monopole problem is solved by inflation (unless M_G is unexpectedly low).

93.9.4 *Flavor violation*

Yukawa interactions of GUT-scale particles with quarks and leptons may leave imprints on the flavor violation induced by SUSY breaking parameters [150]. To understand this, focus first on the MSSM with universal Planck-scale boundary conditions (as e.g. in gravity mediation). Working in a basis where up-quark and lepton Yukawas are diagonal, one finds that the large top-quark Yukawa coupling reduces the l.h. squark mass squareds in the third generation radiatively. It turns out that only the l.h. down-type squark mass matrix has sizable off-diagonal terms in the flavor basis after CKM-rotation. However, in GUTs the color-triplet Higgs has flavor violating interactions from the Yukawa coupling λ_{ij} $(\mathbf{10}_i\ \mathbf{10}_j\ \mathbf{5}_H)$, such that flavor-violating r.h. slepton mass terms are radiatively generated in addition [151]. In $SU(5)$ extension of the type-I seesaw model, where r.h. neutrinos are introduced as $SU(5)$ singlets with interactions λ''_{ij} $(\mathbf{1}_i\ \overline{\mathbf{5}}_j\ \mathbf{5}_H)$, the doublet and color-triplet Higgses acquire another type of Yukawa coupling, respectively. They then radiatively generate flavor-violating l.h. slepton [152] and r.h. down squark masses [153]. These flavor-violating SUSY breaking terms induce new contributions to FCNC processes in quark and lepton sectors, such as $\mu\to e\gamma$ and K^0–$\bar{K}^0$ and B^0–$\bar{B}^0$ mixing. Note that even if the SUSY breaking terms are generated at M_G, the r.h. neutrino Yukawa coupling may induce sizable flavor violation in l.h. slepton masses due to the running between M_G and the right-handed-neutrino mass scale.

EDMs are also induced when both l.h. and r.h. squarks/sleptons have flavor-violating mass terms with relative phases, as discussed for $SO(10)$ in [154] or for $SU(5)$ with r.h. neutrinos in [155]. Thus, such low-energy observables constrain GUT-scale interactions.

93.9.5 *From GUT baryogenesis to leptogenesis and B/L-violating transitions*

During inflation, any conserved quantum number is extremely diluted. Thus, one expects the observed baryon asymmetry of the Universe to originate at reheating or in the subsequent cosmological evolution. In detail, the situation is slightly more involved: Both baryon number B and lepton number L are global symmetries of the SM. However, $(B+L)$ is anomalous and violated by thermal fluctuations in the early Universe, via so-called sphaleron processes. Moreover, it is violated in GUT models, as is most apparent in proton decay. By contrast, $(B-L)$ is anomaly free and preserved by both the SM as well as $SU(5)$ or $SO(10)$ gauge interactions.

Now, the old idea of GUT baryogenesis [156,157] is to generate a $(B+L)$ and hence a baryon asymmetry by the out-of-equilibrium decay of the color-triplet Higgs. However such an asymmetry, generated at GUT temperatures, is washed out by sphalerons[12]. This can be overcome [159] using lepton-number violating interaction of neutrinos to create a $(B$–$L)$ from the $(B$+$L)$ asymmetry, before sphaleron processes become sufficiently fast at $T<10^{12}$ GeV. This $(B-L)$ asymmetry can then survive the subsequent sphaleron dominated phase. Note that this does not work in the minimal SUSY GUT setting, with the triplet Higgs above the GUT scale. The reason is that a correspondingly high reheating temperature would be required which, as explained above, is ruled out by Planck data.

However, the most widely accepted simple way out of the dilemma is to directly generate a net $(B-L)$ asymmetry dynamically in the early Universe, also using r.h. neutrinos. Indeed, we have seen that neutrino oscillations suggest a new scale of physics

[11] Adding extra vector-like sets of fields, e.g. two fermions which only transform under $U(1)$ and have charges Y and $-Y$, is considered to violate minimality.

[12] To be precise, if lepton flavor numbers L_i ($i=1$–3) are nonzero and $(L_i-L_j)\neq0$ ($i\neq j$), one may obtain nonzero values for B and L even if $(B-L)=0$ [158].

of order 10^{14} GeV. This scale is associated with heavy Majorana neutrinos in the seesaw mechanism. If in the early Universe, the decay of the heavy neutrinos is out of equilibrium and violates both lepton number and CP, then a net lepton number may be generated. This lepton number will then be partially converted into baryon number via electroweak processes [160]. This mechanism is called leptogenesis.

If the three heavy Majorana neutrino masses are hierarchical, the net lepton number is produced by decay of the lightest one, and it is proportional to the CP asymmetry in the decay. The CP asymmetry is bounded from above, and the lightest neutrino mass is required to be larger than 10^9 GeV in order to explain the observed baryon asymmetry [161]. This implies that the reheating temperature after inflation should be larger than 10^9 GeV so that the heavy neutrinos are thermally produced[13]. In supersymmetric models, there is a tension between leptogenesis and Big Bang Nucleosynthesis (BBN) if gravitinos decay in the BBN era. The gravitino problem gives a constraint on the reheating temperature $\lesssim 10^{6-10}$ GeV though the precise value depends on the SUSY breaking parameters [163]. Recent reviews of leptogenesis can be found in Ref. [164].

One of the important tests of leptogenesis are searches for neutrinoless double-β ($0\nu\beta\beta$) decays[14]. In a $0\nu\beta\beta$ decay, only two electrons but no (anti-)neutrinos are emitted by the decaying nucleus. This is in contrast to ordinary double-β decay. Thus, $0\nu\beta\beta$ decays are lepton-number-violating with $\Delta L = 2$. At the nucleon level, this is described by dimension-nine effective operators for $nn \to ppee$. These operators may in turn come from SM operators of with dimension less than nine, in combination with SM weak interactions. The lowest one is the dimension-five operator generating the Majorana neutrino mass terms (Eq. (93.17)). Thus, if the lepton-number violating effective interactions come from physics at energies much above the weak scale, the $0\nu\beta\beta$ decay rates are proportional to the Majorana neutrino masses. The latest experimental results are reviewed in [62]. For recent studies of the $0\nu\beta\beta$ decay including SM operators up to mass dimension nine, see [165] and refs. therein.

In addition to L-violation, one can consider $(B-L)$ and B violating phenomena. They are interesting in their own right and may also be relevant to baryogenesis. The relevant operators have higher mass dimension than the familiar dimension-six $(B+L)$-violating operators (cf. Sec. 93.6). They may be predicted in SO(10) GUTs with an intermediate scale, at which baryogenesis is realized, such as in [166]. First, one may have nucleon decays with $\Delta(B-L) = 2$, such as $n \to e^-\pi^+$. This is induced by dimension-seven effective operators in the SM, which are suppressed by the SM Higgs VEV or derivatives. Second, there are neutron-antineutron (n–$\bar{n}$) oscillations, which are induced by $\Delta B = 2$ dimension-nine effective operators in the SM. The upper bound on the mean time for n–$\bar{n}$ transitions is directly derived using free neutrons [167]. It is also constrained from the lower limit on the lifetime for neutrons bound in ^{16}O, derived by Super-Kamiokande [168]. Their results are very similar. Super-Kamiokande also searches for dinucleon decays with $\Delta B = 2$, such as $pp \to \pi^+\pi^+$ and $nn \to \pi^\pm\pi^\mp$ [169].

93.10 Conclusion

Most conservatively, grand unification means that (some of) the SM gauge interactions of $U(1)_Y$, $SU(2)_L$ and $SU(3)_C$ become part of a larger, unifying gauge symmetry at a high energy scale. In most models, especially in the simplest and most appealing variants of $SU(5)$ and $SO(10)$ unification, the statement is much stronger: One expects the three gauge couplings to unify (up to small threshold corrections) at a unique scale, M_G, and the proton to be unstable due to exchange of gauge bosons of the larger symmetry group. Supersymmetric grand unified theories provide, by far, the most predictive and economical framework allowing for perturbative unification. Many more details than could be discussed in the present article can be found in some of the classic reviews [123,170] and the two books [171] (see also [172] for two recent overviews).

Thus, the three classical pillars of GUTs are gauge coupling unification at $M_G \sim 2 \times 10^{16}$ GeV, low-energy supersymmetry (with a large SUSY desert), and nucleon decay. The first of these may be viewed as predicting the value of the strong coupling – a prediction which has already been verified (see Fig. 93.1). Numerically, this prediction remains intact even if SUSY partner masses are somewhat above the weak scale. However, at the conceptual level a continuously increasing lower bound on the SUSY scale is nevertheless problematic for the GUT paradigm: Indeed, if the independent, gauge-hierarchy-based motivation for SUSY is completely abandoned, the SUSY scale and hence α_3 become simply free parameters and the first two pillars crumble. Thus, it is important to keep pushing bounds on proton decay which, although again not completely universal in all GUT constructions, is arguably a more generic part of the GUT paradigm than low-energy SUSY.

Whether or not Yukawa couplings unify is more model dependent. However, irrespective of possible (partial) Yukawa unification, there certainly exists a very interesting and potentially fruitful interplay between flavor model building and grand unification. Especially in the neutrino sector this is strongly influenced by the developing experimental situation.

Another phenomenological signature of grand unification is the strength of the direct coupling of the QCD axion to photons, relative to its coupling to gluons. It is quantified by the predicted anomaly ratio $E/N = 8/3$ (see [173, 174]). This arises in field-theoretic axion models consistent with GUT symmetry (such as DFSZ [175]) and in string-theoretic GUTs [174,176]. In the latter, the axion does not come from the phase of a complex scalar but is a fundamental shift-symmetric real field, coupling through a higher-dimension operator directly to the product of the GUT field-strength and its dual.

It is probably fair to say that, due to limitations of the 4d approach, including especially remaining ambiguities (free parameters or ad hoc assumptions) in models of flavor and GUT breaking, the string theoretic approach has become more important in GUT model building. In this framework, challenges include learning how to deal with the many vacua of the 'landscape' as well as, for each vacuum, developing the tools for reliably calculating detailed, phenomenological observables. Finally, due to limitations of space, the present article has barely touched on the interesting cosmological implications of GUTs. They may become more important in the future, especially in the case that a high inflationary energy scale is established observationally.

[13] This constraint may be avoided in resonant leptogenesis [162], in which the right-handed neutrinos are required to be almost degenerate in mass.

[14] Another important test of leptogenesis would be the observation of CP violation in neutrino oscillations. Strictly speaking, the CP phase in the PMNS matrix does not contribute to ϵ_1 in the seesaw model. Nevertheless, the observation of CP violation in neutrino oscillations would suggest that the seesaw mechanism is associated with a large CP violation, similarly to the quark sector.

94. Leptoquarks

Revised August 2021 by S. Rolli (DOE) and M. Tanabashi (Nagoya U.; KMI, Nagoya U.).

Leptoquarks are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary Standard Model (SM) fermions are dimensionless and invariant under the SM gauge group. Table 94.1 shows the list of all possible quantum numbers with this assumption [1]. The columns of $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 94.1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

Table 94.1: Possible leptoquarks and their quantum numbers.

Spin	$B+L$	$SU(3)_c$	$SU(2)_W$	$U(1)_Y$	Allowed coupling
0	−2	$\bar{3}$	1	1/3	$\bar{q}_L^c \ell_L$ or $\bar{u}_R^c e_R$
0	−2	$\bar{3}$	1	4/3	$\bar{d}_R^c e_R$
0	−2	$\bar{3}$	3	1/3	$\bar{q}_L^c \ell_L$
1	−2	$\bar{3}$	2	5/6	$\bar{q}_L^c \gamma^\mu e_R$ or $\bar{d}_R^c \gamma^\mu \ell_L$
1	−2	$\bar{3}$	2	−1/6	$\bar{u}_R^c \gamma^\mu \ell_L$
0	0	3	2	7/6	$\bar{q}_L e_R$ or $\bar{u}_R \ell_L$
0	0	3	2	1/6	$\bar{d}_R \ell_L$
1	0	3	1	2/3	$\bar{q}_L \gamma^\mu \ell_L$ or $\bar{d}_R \gamma^\mu e_R$
1	0	3	1	5/3	$\bar{u}_R \gamma^\mu e_R$
1	0	3	3	2/3	$\bar{q}_L \gamma^\mu \ell_L$

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible [2,3].

Leptoquark states are expected to exist in various extensions of the SM. The Pati-Salam model [4] is an example predicting the existence of a leptoquark state. Leptoquark states also exist in grand unification theories based on $SU(5)$ [5], $SO(10)$ [6], which includes Pati-Salam color $SU(4)$, and larger gauge groups. Scalar quarks in supersymmetric models with R-parity violation may also have leptoquark-type Yukawa couplings. The bounds on the leptoquark states can therefore be applied to constrain R-parity-violating supersymmetric models. Scalar leptoquarks are expected to exist at the TeV scale in extended technicolor models [7,8] where leptoquark states appear as the bound states of techni-fermions. Compositeness of quarks and leptons also provides examples of models which may have light leptoquark states [9].

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from bounds on leptoquark-induced four-fermion interactions, which are obtained from low-energy experiments, or from collider experiments below threshold. These four-fermion interactions often cause lepton-flavor non-universalities in heavy quark decays. Anomalies observed recently in the R_K and R_D ratios [10–12] in the semi-leptonic B decays may be explained in models with TeV scale leptoquarks.

If a leptoquark couples to quarks (leptons) belonging to more than a single generation in the mass eigenbasis, it can induce four-fermion interactions causing flavor-changing neutral currents (lepton-family-number violations). The quantum number assignment of Table 1 allows several leptoquark states to couple to both left- and right-handed quarks simultaneously. Such leptoquark states are called non-chiral and may cause four-fermion interactions affecting the $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio [13]. Non-chiral scalar leptoquarks also contribute to the muon anomalous magnetic moment [14,15]. Since indirect limits provide more stringent constraints on these types of leptoquarks, it is often assumed that a leptoquark state couples only to a single generation of quarks and a single generation of leptons in a chiral interaction, for which indirect limits become much weaker. Additionally, this assumption gives strong constraints on models of leptoquarks.

Refs. [16–18] give extensive lists of the bounds on the leptoquark-induced four-fermion interactions. For the isoscalar scalar and vector leptoquarks S_0 and V_0, for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds $\lambda^2 < 0.07 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for S_0, and $\lambda^2 < 0.4 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for V_0 ($\lambda^2 < 0.7 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for S_0, and $\lambda^2 < 0.5 \times (M_{\rm LQ}/1\ {\rm TeV})^2$ for V_0) with λ being the leptoquark coupling strength, can be derived from the limits listed in Ref. [19]. The e^+e^- experiments are sensitive to the indirect effects coming from t- and u-channel exchanges of leptoquarks in the $e^+e^- \to q\bar{q}$ process. The HERA experiments give bounds on the leptoquark-induced four-fermion interaction. For detailed bounds obtained in this way, see the Boson Particle Listings for "Indirect Limits for Leptoquarks" and its references.

Collider experiments provide direct limits on the leptoquark states through limits on the pair- and single-production cross sections. The leading-order cross sections of the parton processes

$$\begin{aligned} q + \bar{q} &\to {\rm LQ} + \overline{\rm LQ} \\ g + g &\to {\rm LQ} + \overline{\rm LQ} \\ e + q &\to {\rm LQ} \end{aligned} \tag{94.1}$$

may be written as [20]

$$\begin{aligned} \hat{\sigma}_{\rm LO}\left[q\bar{q} \to {\rm LQ} + \overline{\rm LQ}\right] &= \frac{2\alpha_s^2 \pi}{27\hat{s}}\beta^3, \\ \hat{\sigma}_{\rm LO}\left[gg \to {\rm LQ} + \overline{\rm LQ}\right] &= \frac{\alpha_s^2 \pi}{96\hat{s}} \\ &\quad \times \left[\beta(41 - 31\beta^2) + (18\beta^2 - \beta^4 - 17)\log\frac{1+\beta}{1-\beta}\right], \\ \hat{\sigma}_{\rm LO}\left[eq \to {\rm LQ}\right] &= \frac{\pi\lambda^2}{4}\delta(\hat{s} - M_{\rm LQ}^2) \end{aligned} \tag{94.2}$$

for a scalar leptoquark. Here $\sqrt{\hat{s}}$ is the invariant energy of the parton subprocess, and $\beta \equiv \sqrt{1 - 4M_{\rm LQ}^2/\hat{s}}$. The leptoquark Yukawa coupling is given by λ. Leptoquarks are also produced singly at hadron colliders through $g + q \to {\rm LQ} + \ell$ [21], which allows extending to higher masses the collider reach in the leptoquark search [22], depending on the leptoquark Yukawa coupling. See also Ref. [23] for a comprehensive review on the leptoquark phenomenology in precision experiments and particle colliders.

Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first- (second-, third-) generation leptoquarks.

The LHC, Tevatron and LEP experiments have been searching for pair production of the leptoquark states, which arises from the leptoquark gauge interaction. Due to the typical decay of the leptoquark into charged and neutral leptons and quarks, the searches are carried on in signatures including high p_T charged leptons, high E_T jets and large missing transverse energy. Additionally, searches for pair produced LQs are often organized by the decay mode of the pair of LQs, via the decay parameter β, which represents the branching fraction into a charge lepton vs a neutrino: $\beta = 1$ for both LQs decaying into a charged letpon, $\beta = 0.5$ for one LQ decaying into a charged lepton and one into a neutrino. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 94.1. Since all of the leptoquark states belong to color-triplet representation, the scalar leptoquark pair-production cross section at the Tevatron and LHC can be determined solely as a function of the leptoquark mass without making further assumptions. This is in contrast to the indirect or single-production limits, which give constraints in the leptoquark mass-coupling plane.

Older results from the Tevatron run can be found here: [24–27].

Since the previous version of this review, both ATLAS and CMS have updated their results concerning searches for first, second,

and third generation LQs and leptoquark states which couple only with the i-th generation quarks and the j-th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. The datasets were almost all collected at center of mass energy of 13 TeV and corresponding to the latest integrated luminosity collected before the shutdown of the LHC occurring in 2019 and 2020.

It is worthy to note that organizing LQs by flavor quantum number first before organizing them by gauge quantum number is becoming more common and advantageous because it relates more closely to some of the experimental searches being performed. The traditional nomenclature for 1st, 2nd, and 3rd generation LQ encourages only looking for the diagonal elements in a flavor matrix of possibilities, which has been the traditional experimental search strategy.

Current results extend previous mass limits for scalar leptoquarks to $>$ 1435 GeV (first generation, CMS, β =1, $\sqrt{s}$ = 13 TeV) and $>$ 1270 GeV(first generation, CMS, β =0.5,$\sqrt{s}$ = 13 TeV) [28]; $>$ 1800 GeV (first generation, ATLAS, β =1, $\sqrt{s}$ = 13 TeV) [29] and $>$ 1290 GeV (first generation, ATLAS, β =0.5, $\sqrt{s}$ = 13 TeV) [30]; $>$ 1530 GeV (second generation, CMS, β =1, $\sqrt{s}$ = 13 TeV) and $>$ 1285 GeV (second generation, CMS, β =0.5, $\sqrt{s}$ = 13 TeV) [31]; and $>$ 1700 GeV (second generation, ATLAS, β =1,$\sqrt{s}$ = 13 TeV) [29] and $>$ 1230 GeV (second generation, ATLAS, β =0.5,$\sqrt{s}$ = 13 TeV) [30]. All limits are presented at 95% C.L.

As for third generation leptoquarks, CMS results are the following: 1) assuming that all leptoquarks decay to a top quark and a τ lepton, the existence of pair produced, third-generation leptoquark up to a mass of 900 GeV (β =1, 13 TeV) is excluded at 95% confidence level [32]; 2) assuming that all leptoquarks decay to a bottom quark and a τ lepton, the existence of pair produced, third-generation leptoquark up to a mass of 1020 GeV (β =1, 13 TeV) is excluded at 95% confidence level [33]; 3)assuming that all leptoquarks decay to a bottom quark and a τ neutrino, the existence of pair produced, third-generation leptoquark up to a mass of 450 GeV (β =0, 7 TeV)is excluded at 95% confidence level [34]. In a recent paper [35] signatures of top quark τ lepton ν bottom and top τ ν - not previously explored in dedicated searches, were analyzed in the context of searches for scalar leptoquark of charge -1/3e coupling to a top quark plus a τ lepton (tτ) or a bottom quark plus a neutrino (bν), or a vector particle of charge +2/3e, coupling to tν or bτ. These choices are motivated by models that can explain a series of anomalies observed in the measurement of B meson decays. The data are found to be in agreement with the standard model prediction. Lower limits at 95% confidence level are set on the LQ mass in the range 0.98–1.73 TeV, depending on the LQ spin and its coupling λ to a lepton and a quark, and assuming equal couplings for the two LQ decay modes considered. These are the most stringent constraints to date on the existence of leptoquarks in this scenario.

In [36], the ATLAS collaboration has limits on pair production of third generation scalar leptoquarks where all possible decays of the leptoquark into a quark (t, b) and a lepton (τ, ν) of the third generation are considered. The limits are presented as a function of the leptoquark mass and the branching ratio into charged leptons for leptoquark of up-type ($LQ_3^{up} \rightarrow \tau\nu/b\tau$) and down-type ($LQ_3^{d} \rightarrow b\nu/t\tau$); many results are re-interpretation of previously published ATLAS searches. The collaboration finds that masses below 800 GeV are excluded for both LQ_3^u and LQ_3^d independently of the branching ratio, with masses below about 1 TeV being excluded for the limiting cases of branching ratios equal to zero or unity. In a more recent paper [37] ATLAS present the result of searches for pair production of third-generation scalar leptoquarks decaying into a top quark and a τ-lepton, using 139 fb^{-1} of data collected at 13 TeV. Scalar leptoquarks decaying exclusively into tτ are excluded up to masses of 1.43 TeV while, for a branching fraction of 50% into tτ , the lower mass limit is 1.22 TeV.

It is also possible to consider leptoquark states which couple only with the i-th generation quarks and the j-th generation leptons ($i \neq j$) without causing conflicts with severe indirect constraints. Such couplings have received renewed attention because they may provide an explanation to anomalies in rare $B-meson$ decays and the anomalous magnetic moment of the muon. See Ref. [38, 39] and [40] and references therein for collider search strategies and limits on the pair production cross sections of this class of leptoquark states. In this framework, a novel CMS result [41] presents a non-traditional search for pair production of LQs coupled to a top quark and a muon. As no deviation from the Standard Model prediction was observed, scalar LQs decaying exclusively into $top-\mu$ are excluded up to masses of 1420 GeV. In a recent ATLAS paper [42] a search for pair production of scalar lepto- quarks, each decaying into either an electron or a muon and a top quark, is presented. This is the first leptoquark search using ATLAS data to investigate top-philic cross- generational couplings that could provide explanations for recently observed anomalies in B meson decays. In the absence of any s ignificant deviation from the background expectation, lower limits on the leptoquark masses are set at 1480 GeV and 1470 GeV for the electron and muon channel, respectively.

The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are not determined even if we fix its gauge quantum numbers as listed in the Table 94.1 [43]. The production of vector leptoquarks depends in general on additional assumptions, where the leptoquark couplings and their pair production cross sections are enhanced relative to the scalar leptoquark contributions. The most stringent limits on vector LQ production are now from CMS [44] where previous searches for squarks and gluinos have been reinterpreted to constrain models of leptoquark production. LQ masses below 1530 GeV are excluded assuming the Yang-Mills case with coupling $\kappa = 1$, or 1115 GeV in the minimal coupling case where $\kappa = 0$, placing the most stringent constraint to date from pair production of vector LQs.

The leptoquark pair-production cross sections in e^+e^- collisions depend on the leptoquark $SU(2) \times U(1)$ quantum numbers and Yukawa coupling with electron [45].

Searches for first generation leptoquark singly produced were performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the leptoquark mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling $\lambda = 0.1$, early ZEUS Collaboration bounds on the first-generation leptoquarks range from 248 to 290 GeV, depending on the leptoquark species [46]. The ZEUS Collaboration has recently released a new paper [47] where data corresponding to a luminosity of around 1 fb^{-1} have been used in the framework of $eeqq$ contact interactions (CI) to set limits on possible high-energy contributions beyond the Standard Model to electron-quark scattering. The analysis of the ep data has been based on simultaneous fits of parton distribution functions including contributions of Contact Interaction (CI) couplings to ep scattering. Several general CI models and scenarios with heavy leptoquarks were considered. As unambiguous deviations from the SM cannot be established, limits for CI compositeness scales and LQ mass scales were set that are in the TeV range. The H1 Collaboration has a comprehensive summary of searches for first generation leptoquarks using the full data sample collected in ep collisions at HERA (446 pb^{-1}). No evidence of production of leptoquarks was observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength $\lambda = 0.3$, first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [48].

At the LHC, the CMS collaboration performed searches for single production of first and second generation leptoquarks [49], which is complementary to the HERA searches in the high λ region (for coupling strength $\lambda = 1.0$, first generation leptoquarks are excluded for masses up to 1.73 TeV and second generation leptoquark are excluded up to masses of 530 GeV). CMS also recently searched for third generation LQ decaying into τ and *bottom* in [50]. Assuming unit Yukawa coupling (λ), a third generation scalar leptoquark is excluded for masses below 740 GeV. Limits are also set on λ of the hypothesized leptoquark as a function of its mass. Above $\lambda = 1.4$, the results provide the best upper limit on the mass of a third-generation scalar leptoquark decaying to a τ lepton and a bottom quark.

Searches for LQ will continue with more LHC data, particularly in light of the renewed interest in this type of particle to explain violation of lepton flavor universality and other anomalies, which point to explanations laying outside the Standard Model.

95. Magnetic Monopoles

Revised August 2021 by D. Milstead (Stockholm U.) and E.J. Weinberg (Columbia U.).

95.1 Theory of magnetic monopoles

The symmetry between electric and magnetic fields in the source-free Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge Q_M and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi}\frac{\hat{\mathbf{r}}}{r^2}\,. \tag{95.1}$$

Any vector potential $\mathbf{A}$ whose curl is equal to $\mathbf{B}$ must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge Q_E would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of 2π. Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges $Q_E^{\rm min}$ and $Q_M^{\rm min}$ obeying

$$Q_E^{\rm min}Q_M^{\rm min} = 2\pi\,. \tag{95.2}$$

(For monopoles which also carry an electric charge, called dyons [2], the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r}\times\mathbf{v} - 4\pi Q_E Q_M\hat{\mathbf{r}} \tag{95.3}$$

Requiring the radial component of $\mathbf{L}$ to be quantized in half-integer units yields Eq. 95.2.

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [3, 4]. For example, a monopole could have both a U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (95.2). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. 95.2 and conclude that Q_M must be a multiple of $6\pi/e$.

The prediction of GUT monopoles arises from the work of 't Hooft [5] and Polyakov [6], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field ϕ breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass M_V to two of the gauge bosons. In order to have finite energy, ϕ must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude v of $\langle\phi\rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of ϕ in internal space is correlated with the position in physical space; *i.e.*, $\phi^a \sim v\hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of ϕ requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\rm mon} \sim \frac{4\pi M_V}{e^2}\,. \tag{95.4}$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the standard electroweak theory, with $\mathrm{SU(2)}\times\mathrm{U(1)}$ broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions. Although electroweak scale monopoles are thus not required, there have been claims that they might not be ruled out. For example, there have been a variety of proposals in this direction involving modifications of the Lagrangian.

The second case is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. Here the spectrum of states must include a topologically stable monopole whose mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\mathrm{SU(5)} \xrightarrow{M_X} \mathrm{SU(3)}\times\mathrm{SU(2)}\times\mathrm{U(1)} \xrightarrow{M_W} \mathrm{SU(3)}\times\mathrm{U(1)} \tag{95.5}$$

has a monopole [7] with $Q_M = 2\pi/e$ and mass

$$M_{\rm mon} \sim \frac{4\pi M_{\rm X}}{g^2}\,, \tag{95.6}$$

where g is the SU(5) gauge coupling. For a unification scale of 10^{16} GeV, these monopoles would have a mass $M_{\rm mon} \sim 10^{17}$ – 10^{18} GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$\mathrm{SO(10)} \xrightarrow{M_1} \mathrm{SU(4)}\times\mathrm{SU(2)}\times\mathrm{SU(2)} \xrightarrow{M_2} \mathrm{SU(3)}\times\mathrm{SU(2)}\times\mathrm{U(1)} \tag{95.7}$$

there is monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [8].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon–monopole scattering. The surprising feature, pointed out by Callan [9] and Rubakov [10], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as p + monopole $\to e^+ + \pi^0$ + monopole are essentially geometric; *i.e.*, $\sigma_{\Delta B}\beta \sim 10^{-27}$ cm^2, where $\beta = v/c$. Note, however, that this catalysis is model-dependent and is not even a universal property of all GUT monopoles.

95.2 Production and Annihilation

GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early Universe as topological defects arising via the Kibble mechanism [11] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [12]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

95.3 Astrophysical and Cosmological Bounds

If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu$G. A monopole with the Dirac charge and mass M would be accelerated by this field to a velocity

$$v_{\rm mag} \sim \begin{cases} c, & M \lesssim 10^{11}{\rm GeV}\,, \\ 10^{-3}c\left(\frac{10^{17}\,{\rm GeV}}{M}\right)^{1/2}, & M \gtrsim 10^{11}{\rm GeV}\,. \end{cases} \quad (95.8)$$

Accelerating these monopoles drains energy from the magnetic field. Parker [13] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. [14] for details), this Parker bound is

$$F < \begin{cases} 10^{-15}\,{\rm cm}^{-2}\,{\rm sr}^{-1}\,{\rm sec}^{-1}\,, & M \lesssim 10^{17}\,{\rm GeV}\,, \\ 10^{-15}\left(\frac{M}{10^{17}\,{\rm GeV}}\right){\rm cm}^{-2}\,{\rm sr}^{-1}\,{\rm sec}^{-1}\,, & M \gtrsim 10^{17}\,{\rm GeV}\,. \end{cases} \quad (95.9)$$

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [15],

$$F < \left[\frac{M}{10^{17}{\rm GeV}} + (3\times 10^{-6})\right] 10^{-16}\,{\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \quad (95.10)$$

Considering magnetic fields in galactic clusters gives a bound [16] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the Universe. If the monopole mass density is a fraction $\Omega_{\rm M}$ of the critical density, and the monopoles were uniformly distributed throughout the Universe, there would be a monopole flux

$$F_{\rm uniform} = 1.3{\times}10^{-16}\Omega_{\rm M}\left(\frac{10^{17}\,{\rm GeV}}{M}\right)\left(\frac{v}{10^{-3}c}\right){\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \quad (95.11)$$

If we assume that $\Omega_{\rm M} \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of $\Omega_{\rm M}$, and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [17–21] , white dwarfs [22], and Jovian planets [23] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; *e.g.*, on how much the accumulated density is reduced by monopole-antimonopole annihilation, and on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\left(\frac{\sigma_{\Delta B}\beta}{10^{-27}{\rm cm}^2}\right) \sim (10^{-18} - 10^{-29}){\rm cm}^{-2}{\rm sr}^{-1}{\rm sec}^{-1}. \quad (95.12)$$

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of the above equation.

95.4 Searches for Magnetic Monopoles

To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be $Q_e^m < 10^{-24}Q_M^D$ [24] (where Q_M^D is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass [1] [25]. Nevertheless, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in matter [26]. Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

95.5 Search Techniques

Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [27, 28].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

95.5.1 *Searches for Monopoles Bound in Matter*

Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [29, 30]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [30].

95.5.2 *Searches in Cosmic Rays*

Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Searches made assuming a catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [31] or assigned a modest value (1mb) [32].

Although early cosmic ray searches using the induction technique [33] and NTDs [34] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim$ 10000m^2 for an isotropic flux. As shown in Fig. 95.1, this experiment has so far provided the most extensive β-dependent flux limits for GUT monopoles with Dirac charge [32]. Also shown

[1] Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

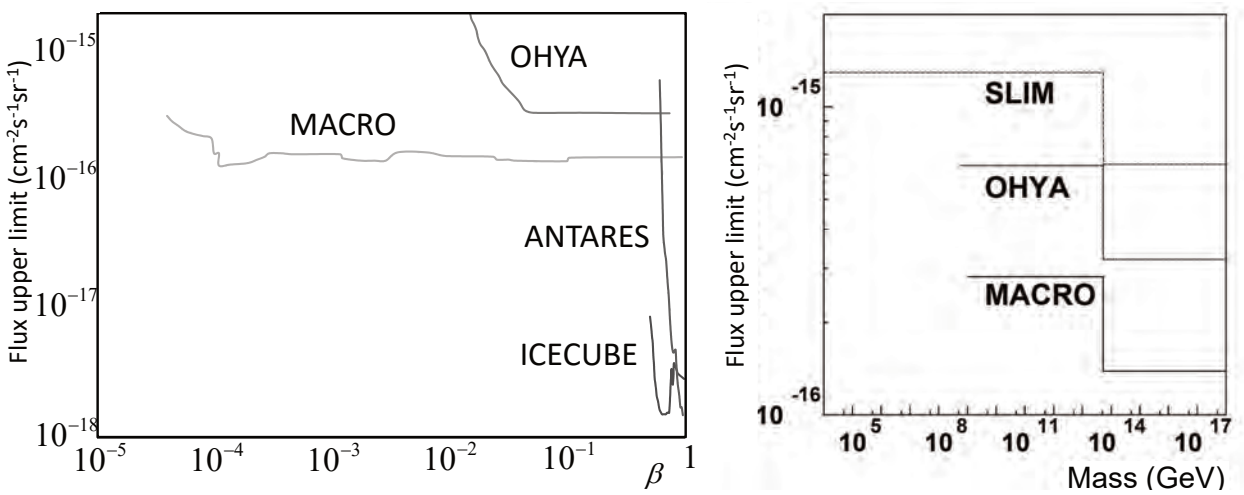

Figure 95.1: Upper flux limits for (left) GUT monopoles as a function of β (right) Monopoles as a function of mass for $\beta > 0.05$.

are limits from an experiment at the OHYA mine in Japan [31], which used a 2000m^2 array of NTDs.

In Fig. 95.1, upper flux limits are also shown as a function of mass for monopole speed $\beta > 0.05$. In addition to MACRO and OYHA flux limits, results from the SLIM [35] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles ($10^5 \lesssim M \lesssim 10^{12}$ GeV). In addition to the results shown in Fig. 95.1, limits as low as $\sim 1.5 \times 10^{-18}$ cm^{-2}s^{-1}sr^{-1} were obtained for monopoles with $\beta > 0.51$ and $\beta > 0.6$ by the IceCube [36] and Antares [37] experiments, respectively. Furthermore, the NoVA experiment [38] has recently set an upper limit on monopole flux of 2×10^{-14} cm^{-2}s^{-1}sr^{-1} for speeds $6 \times 10^{-4} < \beta < 10^{-3}$ for masses greater thsan 5×10^8 GeV. Stringent constraints on the flux of ultra-relativistic monopoles have been obtained at the Pierre Auger Observatory [39] which was sensitive to monopoles with γ values ranging from 10^9 to 10^{12}, leading to flux limits in the range $10^{-15} - 2.5 \times 10^{-21}$ cm^{-2}s^{-1}sr^{-1}. The RICE [40] and ANITA-II experiments [41] at the South Pole have also sought ultra-relativistic monopoles with γ values of $10^7 \lesssim \gamma \lesssim 10^{12}$ and $10^9 \lesssim \gamma \lesssim 10^{13}$, respectively, and which produced flux limits as low as 2.5×10^{-21} cm^{-2}s^{-1}sr^{-1}.

95.5.3 *Searches via the Catalysis of Nucleon-Decay*

Searches have been performed for evidence of the catalysed decay of a nucleon by a monopole, as predicted by the Callan-Rubakov mechanism. The searches are thus sensitive to the assumed value of the catalysis decay cross section. Searches have been made with the Soudan [42] and Macro [43] experiments, using tracking detectors. Searches at IMB [44], the underwater Lake Baikal experiment [45] and the The IceCube experiment [46] which exploit the Cerenkov effect have also been made. The resulting β-dependent flux limits from these experiments typically vary between $\sim 10^{-18}$ and $\sim 10^{-14}$cm^{-2}sr^{-1}s^{-1}. A recent search for low energy neutrinos (assumed to be produced from induced proton decay in the sun) was made at Super-Kamiokande [47]. A model- and β-dependent of limit of $6.3 \times 10^{-24}(\frac{\beta}{10^{-3}})^2$cm^{-2}sr^{-1}s^{-1} was obtained.

95.5.4 *Searches at Colliders*

Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

95.5.4.1 *Direct Searches at Colliders*

Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopole-antimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass regions. A conservative approach with as little model-dependence as possible is thus to present representative values of the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 95.2 for recent results from high energy colliders.

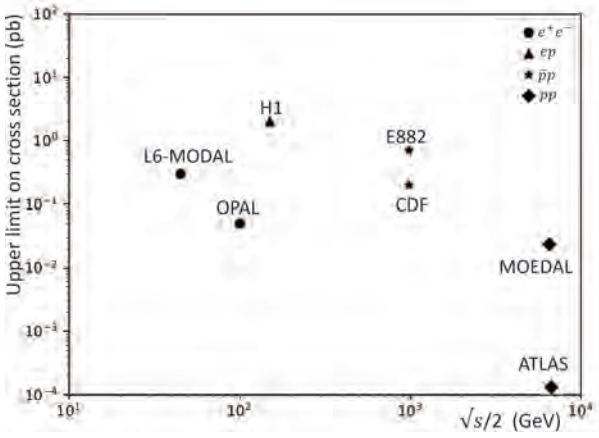

Figure 95.2: Upper limits on the production cross sections of monopoles from various collider-based experiments.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made in pp collisions at the LHC by the ATLAS [48, 49] and MoEDAL [50, 51] experiments. The experiments looked for highly ionising particles leaving characteristic energy deposition profiles and stopped monopoles with the induction method, respectively. The charge-dependent mass limits extend up to around 4 TeV. The ATLAS work considers monopoles with $0.5Q_M^D$ and $2Q_M^D$ while MoEDAL quotes limits for monopoles with charges from Q_M^D to $5Q_M^D$. MoEDAL considered monopole-pair production via photon fusion along with, as is commonly used in hadron-hadron collisions, Drell-Yan processes [52]. Tevatron searches have also been carried out by the CDF [53] and E882 [54] experiments. The CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF

and D0 detectors using periods of luminosity. Earlier searches at the Tevatron, such as [55], used NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [56] and searches for trapped monopoles [57].

The only LEP-2 search was made by OPAL [58] which quoted cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to ~ 45 GeV. The L6-MODAL experiment [59] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as $0.1Q_M^D$ [60]. The deployment of NTDs around the beam interaction point was also used at earlier e^+e^- colliders such as KEK [61] and PETRA [62]. Searches at e^+e^- facilities have also been made for particles following non-helical trajectories [63,64].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method, monopoles were sought which could have stopped in the aluminium beampipe which had been used by the H1 experiment at HERA [65]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

95.5.4.2 *Indirect Searches at Colliders*

It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [66,67]. Photon-based searches were made by the D0 [68] and L3 [69] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However, it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

INDEX

Index

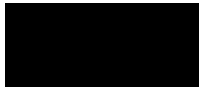
This index is for the complete *Review of Particle Physics* (Volume 1 and 2). Page numbers larger than 1122 refer to the Particle Listings in Volume 2 that can be found in the journal publication and online at `https://pdg.lbl.gov`.

VOLUME II: TABLE OF CONTENTS

PARTICLE LISTINGS*

*The divider sheets give more detailed indices for each main section of the Particle Listings.

INTRODUCTION TO THE PARTICLE LISTINGS



Illustrative Key to the Particle Listings

Name of particle. "Old" name used before 1986 renaming scheme also given if different. See the section "Naming Scheme for Hadrons" for details.

$a_0(1200)$

$I^G(J^{PC}) = 1^-(0^{++})$ — Particle quantum numbers (where known).

OMITTED FROM SUMMARY TABLE — Indicates particle omitted from Particle Physics Summary Table, implying particle's existence is not confirmed.

Evidence not compelling, may be a kinematic effect.

Quantity tabulated below.

$a_0(1200)$ MASS

General comments on particle.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
1206± 7 OUR AVERAGE						
1210± 8±9	3000	FENNER	87	MMS	−	3.5 $\pi^- p$
1198±10		PIERCE	83	ASPK	+	2.1 $K^- p$
1216±11±9	1500	[1] MERRILL	81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •						
1192±16	200	LYNCH	81	HBC	±	2.7 $\pi^- p$

Top line gives our best value (and error) of quantity tabulated here, based on weighted average of measurements used. Could also be from fit, best limit, estimate, or other evaluation. See next page for details.

"Document id" for this result; full reference given below.

Footnote number linking measurement to text of footnote.

Measurement technique. (See abbreviations on next page.)

[1] Systematic error was added quadratically by us in our 1986 edition.

$a_0(1200)$ WIDTH

Number of events *above background*.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	CHG	COMMENT
41±11 OUR AVERAGE Error includes scale factor of 1.8. See the ideogram below.						
50± 8		PIERCE	83	ASPK	+	2.1 $K^- p$
70^{+30}_{-20}	200	LYNCH	81	HBC	±	2.7 $\pi^- p$
25± 5±7		MERRILL	81	HBC	0	3.2 $K^- p$
• • • We do not use the following data for averages, fits, limits, etc. • • •						
<60		FENNER	87	MMS	−	3.5 $\pi^- p$

Measured value used in averages, fits, limits, etc.

Scale factor > 1 indicates possibly inconsistent data.

Reaction producing particle, or general comments.

Error in measured value (often statistical only; followed by systematic if separately known; the two are combined in quadrature for averaging and fitting.)

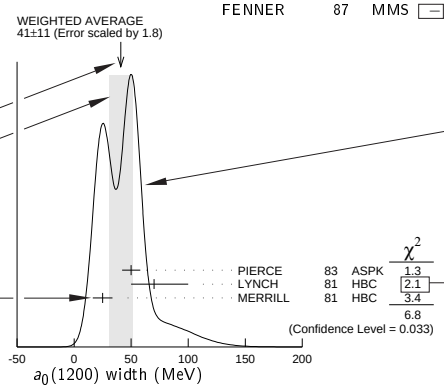
"Change bar" indicates result added or changed since previous edition.

Charge(s) of particle(s) detected.

Measured value *not used* in averages, fits, limits, etc. See the Introductory Text for explanations.

Arrow points to weighted average.

Shaded pattern extends $\pm 1\sigma$ (scaled by "scale factor" S) from weighted average.



Ideogram to display possibly inconsistent data. Curve is sum of Gaussians, one for each experiment (area of Gaussian = 1/error; width of Gaussian = ±error). See Introductory Text for discussion.

Value and error for each experiment.

Contribution of experiment to χ^2 (if no entry present, experiment not used in calculating χ^2 or scale factor because of very large error).

$a_0(1200)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1 3π	(65.2±1.3) %	S=1.7
Γ_2 $K\overline{K}$	(34.8±1.3) %	S=1.7
Γ_3 $\eta\pi^\pm$	< 5 $\times 10^{-4}$	CL=95%

Partial decay mode (labeled by Γ_i).

Our best value for branching fraction as determined from data averaging, fitting, evaluating, limit selection, etc. This list is basically a compact summary of results in the Branching Ratio section below.

$a_0(1200)$ BRANCHING RATIOS

Branching ratio.

$\Gamma(3\pi)/\Gamma_{total}$ — Γ_1/Γ

VALUE	DOCUMENT ID		TECN	CHG	COMMENT
0.652±0.013 OUR FIT Error includes scale factor of 1.7.

VALUE (units 10^{-4})	CL%	DOCUMENT ID		TECN	CHG	COMMENT
<3.5	95	PIERCE	83	ASPK	+	2.1 $K^- p$

Confidence level for measured upper limit.

$a_0(1200)$ REFERENCES

References, ordered inversely by year, then author.

FENNER	87	PRL 55 14	H. Fenner *et al.*	(SLAC)
PIERCE	83	PL 123B 230	J.H. Pierce	(FNAL) JP
LYNCH	81	PR D24 610	G.R. Lynch *et al.*	(CLEO Collab.)
MERRILL	81	PRL 47 143	D.W. Merrill *et al.*	(SACL, CERN)

"Document id" used on data entries above.

Partial list of author(s) in addition to first author.

Quantum number determinations in this reference.

Journal, report, preprint, etc. (See abbreviations on next page.)

Institution(s) of author(s). (See abbreviations on next page.)

Abbreviations Used in the Particle Listings

Indicator of Procedure Used to Obtain Our Result

OUR AVERAGE	From a weighted average of selected data.
OUR FIT	From a constrained or overdetermined multiparameter fit of selected data.
OUR EVALUATION	Not from a direct measurement, but evaluated from measurements of other quantities.
OUR ESTIMATE	Based on the observed range of the data. Not from a formal statistical procedure.
OUR LIMIT	For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

Measurement Techniques (i.e., Detectors and Methods of Analysis)

A1	A1 Collaboration at MAMI
A2MM	A2 spectrometer at the Mainz Microtron, MAMI
ABRA	ABRACADABRA QCD axion dark matter search
ACCM	ACCMOR Collaboration
ADMX	Axion Dark Matter Experiment
AEMS	Argonne effective mass spectrometer
ALEP	ALEPH – CERN LEP detector
ALPS	Photon regeneration experiment
AMND	AMANDA South Pole neutrino detector
AMY	AMY detector at KEK-TRISTAN
ANAI	Direct DM detection exp. with NaI at Canfranc Underground Lab, Spain
ANIC	ANTARES and IceCube combined analysis
ANIT	Antarctic Impulsive Transient Antenna balloon mission
ANTR	ANTARES underwater neutrino telescope in the Western Mediterranean Sea
APEX	FNAL APEX Collab.
ARG	ARGUS detector at DORIS
ARGD	Fit to semicircular amplitude path on Argand diagram
ASP	Anomalous single-photon detector
ASPK	Automatic spark chambers
ASTE	ASTERIX detector at LEAR
ASTR	Astronomy
ATLS	ATLAS detector at CERN LHC
AUGE	Pierre Auger Observatory
AURG	Resonant-mass gravitational wave AURIGA detector
B787	BNL experiment 787 detector
B791	BNL experiment 791 detector
B845	BNL experiment 845 detector
B852	BNL E-852
B865	BNL E865 detector
B871	BNL experiment 871 detector
B949	BNL E949 detector at AGS
BABR	BaBar Collab.
BAIK	Lake Baikal neutrino telescope
BAKS	Baksan underground scintillation telescope
BC	Bubble chamber
BDMP	Beam dump
BEAT	CERN BEATRICE Collab.
BEBC	Big European bubble chamber at CERN
BEL2	Belle II Collab.
BELL	Belle Collab.
BES	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES2	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BES3	BES Beijing Spectrometer at Beijing Electron-Positron Collider
BIS2	BIS-2 spectrometer at Serpukhov
BKEI	BENKEI spectrometer system at KEK Proton Synchroton
BOLO	Bolometer, a cryogenic thermal detector
BONA	Bonanza nonmagnetic detector at DORIS
BORX	BOREXINO
BPWA	Barrelet-zero partial-wave analysis
C100	COSINE-100 experiment in South Korea
CALO	Calorimeter
CASK	CULTASK: CAPPs Ultra Low Temperature Axion Search in Korea
CASP	Cosmic Axion Spin Precession Experiments
CAST	CAST experiment at CERN
CBAL	Crystal Ball detector at SLAC-SPEAR or DORIS
CBAR	Crystal Barrel detector at CERN-LEAR
CBOX	Crystal Box at LAMPF
CBTP	CBELSA/TAPS Collaboration
CC	Cloud chamber
CCFR	Columbia-Chicago-Fermilab-Rochester detector
CDEX	China Dark Matter Experiment
CDF	Collider detector at Fermilab
CDF2	CDF-II Collab.
CDHS	CDHS neutrino detector at CERN
CDM2	CDMS II, Cryogenic Dark Matter Search at Soudan Underground Lab.
CDMS	CDMS Collaboration
CELL	CELLO detector at DESY
CGNT	CoGeNT dark matter search experiment
CHER	Cherenkov detector
CHM2	CHARM-II neutrino detector (glass) at CERN
CHOZ	Nuclear Power Station near Chooz, France
CHRM	CHARM neutrino detector (marble) at CERN
CHRS	CHORUS Collaboration – CERNS SPS
CIB	Cosmic Infrared Background
CIBS	CERN-IHEP boson spectrometer
CLAS	Jefferson CLAS Collab.
CLE2	CLEO II detector at CESR
CLE3	CLEO III detector at CESR
CLEC	CLEO-c detector at CESR
CLEO	Cornell magnetic detector at CESR
CMB	Cosmic Microwave Background
CMD	Cryogenic magnetic detector at VEPP-2M, Novosibirsk
CMD2	Cryogenic magnetic detector 2 at VEPP-2M, Novosibirsk
CMD3	Cryogenic magnetic detector 3 at VEPP-2000, Novosibirsk
CMS	CMS detector at CERN LHC
CNTR	Counters
COMB	Combined analysis of data from independent experiments.
COMP	COMPASS experiment at the CERN SPS
CONN	CONNIE: Coherent Neutrino-Nucleus Interaction Experiment
COSM	Cosmology and astrophysics
COSY	COSY-TOF Collaboration
COUP	COUPP (the Chicagoland Observatory for Underground Particle Physics) Collab.
CPLR	CPLEAR Collaboration
CRBT	Crystal Ball and TAPS detector at MAMI
CRES	CRESST cryogenic detector
CRYB	Crystal Ball at BNL
CRYM	Crystal Ball detector at Mainz Microtron MAMI
CSB2	Columbia U. - Stony Brook BGO calorimeter inserted in NaI array
CSME	COSME Collaboration
CUOR	CUORICINO experiment at Gran Sasso Laboratory.
CUSB	Columbia U. - Stony Brook segmented NaI detector at CESR
D0	D0 detector at Fermilab Tevatron Collider
DAMA	DAMA, dark matter detector at Gran Sasso National Lab.
DASP	DESY double-arm spectrometer
DAYA	Daya Bay Collaboration
DBC	Deuterium bubble chamber
DCHZ	Double Chooz Collaboration
DEAP	DEAP-3600 DM search with argon at SNOLAB
DISP	Graviton mass measurement based on dispersion measure
DLCO	DELCO detector at SLAC-SPEAR or SLAC-PEP
DLPH	DELPHI detector at LEP
DM1	Magnetic detector no. 1 at Orsay DCI collider
DM2	Magnetic detector no. 2 at Orsay DCI collider
DMIC	DAMIC Dark Matter in CCD experiment at Fermilab
DMTP	Dark Matter Time Projection Chamber (DMTPC) directional detection experiment
DONU	DONUT Collab.
DPWA	Energy-dependent partial-wave analysis
DRFT	Directional dark matter detector at Boulby Underground Science Facility
DS50	DarkSide-50 Liquid Argon TPC at Gran Sasso National Laboratory
E137	SLAC E137 beam-dump experiment
E621	Fermilab E621 detector
E653	Fermilab E653 detector
E665	Fermilab E665 detector
E687	Fermilab E687 detector
E691	Fermilab E691 detector
E705	Fermilab E705 Spectrometer-Calorimeter
E731	Fermilab E731 Spectrometer-Calorimeter
E756	Fermilab E756 detector
E760	Fermilab E760 detector
E761	Fermilab E761 detector
E771	Fermilab E771 detector
E773	Fermilab E773 Spectrometer-Calorimeter
E789	Fermilab E789 detector
E791	Fermilab E791 detector

E799	Fermilab E799 Spectrometer-Calorimeter
E835	Fermilab E835 detector
EDE2	EDELWEISS II dark matter search Collaboration
EDE3	EDELWEISS III dark matter search Collaboration
EDEL	EDELWEISS dark matter search Collaboration
EDGS	EDGES: Global EoR (Epoch of Reionization) Signature experiment
EHS	Four-pi detector at CERN
ELEC	Electronic combination
EMC	European muon collaboration detector at CERN
EMUL	Emulsions
ESR	Electron spin resonance spectroscopy
FAST	Fiber Active Scintillator Target detector at PSI
FBC	Freon bubble chamber
FENI	FENICE (at the ADONE collider of Frascati)
FIT	Fit to previously existing data
FLAT	Large Area Telescope onboard the Fermi Gamma-Ray Space Telescope (Fermi-LAT)
FMPS	Fermilab Multiparticle Spectrometer
FOCS	FNAL E831 FOCUS Collab.
FRAB	ADONE $B\overline{B}$ group detector
FRAG	ADONE $\gamma\gamma$ group detector
FRAM	ADONE MEA group detector
FREJ	FREJUS Collaboration – modular flash chamber detector (calorimeter)
FUNK	Finding U(1)'s of a Novel Kind experiment
GA24	Hodoscope Cherenkov γ calorimeter (IHEP GAMS-2000) (CERN GAMS-4000)
GALX	GALLEX solar neutrino detector in the Gran Sasso Underground Lab.
GAM2	IHEP hodoscope Cherenkov γ calorimeter GAMS-2000
GAM4	CERN hodoscope Cherenkov γ calorimeter GAMS-4000
GAMS	IHEP hodoscope Cherenkov γ calorimeter GAMS-4π
GNME	Global Network of Optical Magnetometers for Exotic searches (GNOME)
GNO	Gallium Neutrino Observatory in the Gran Sasso Underground Lab.
GOLI	CERN Goliath spectrometer
GRAL	GRAAL Collaboration
H1	H1 detector at DESY/HERA
HAWC	High Altitude Water Cherenkov Observatory experiment at Sierra Negra, Mexico
HBC	Hydrogen bubble chamber
HDBC	Hydrogen and deuterium bubble chambers
HDES	HADES Collaboration at GSI in Darmstadt
HDMO	Heidelberg-Moscow Experiment
HDMS	Heidelberg Dark Matter Search Experiment
HEBC	Helium bubble chamber
HEPT	Helium proportional tubes
HERA	H1 and ZEUS Collaborations at DESY/HERA
HERB	HERA-B detector at DESY/HERA
HERM	HERMES detector at DESY/HERA
HESS	High Energy Stereoscopic System gamma-ray instrument
HFR	HighFlow Reactor at the Institut Laue-Langevin
HFS	Hyperfine structure
HLBC	Heavy-liquid bubble chamber
HOME	Homestake underground scintillation detector
HPGE	High-purity Germanium detector
HPS	Heavy Photon Search experiment at JLAB
HPW	Harvard-Pennsylvania-Wisconsin detector
HRS	SLAC high-resolution spectrometer
HYBR	Hybrid: bubble chamber + electronics
HYCP	HyperCP Collab. (FNAL E-871)
HYST	HAYSTAC axion search experiment
IACT	Imaging Air Cherenkov Telescope
ICAR	ICARUS experiment at Gran Sasso Laboratory.
ICCB	IceCube neutrino detector at South Pole
IGEX	IGEX Collab.
IMB	Irvine-Michigan-Brookhaven underground Cherenkov detector
IMB3	Irvine-Michigan-Brookhaven underground Cherenkov detector
INDU	Magnetic induction
IPWA	Energy-independent partial-wave analysis
ISTR	IHEP ISTRA+ spectrometer-calorimeter
JADE	JADE detector at DESY
JPAC	Joint Physics Analysis Center (JPAC) Collaboration
K246	KEK E246 detector with polarimeter
K2K	KEK to Super-Kamiokande
K391	KEK E391a detector
K470	KEK-E470 Stopping K detector
KAM2	KAMIOKANDE-II underground Cherenkov detector
KAMI	KAMIOKANDE underground Cherenkov detector
KAR2	KARMEN2 calorimeter at the ISIS neutron spallation source at Rutherford
KARM	KARMEN calorimeter at the ISIS neutron spallation source at Rutherford
KEDR	detector operating at VEPP-4M collider (Novosibirsk)
KIMS	Korea Invisible Mass Search experiment at YangYang, Korea
KLND	KamLand Collab. (Japan)
KLOE	KLOE detector at DAFNE (the Frascati e+e- collider Italy)
KOLR	Kolar Gold Field underground detector
KOTO	KOTO experiment with K_L^0 beam at J-PARC
KTEV	KTeV Collaboration
L3	L3 detector at LEP
LASR	Laser
LASS	Large-angle superconducting solenoid spectrometer at SLAC
LATT	Lattice calculations
LEBC	Little European bubble chamber at CERN
LEGS	BNL LEGS Collab.
LENA	Nonmagnetic lead-glass NaI detector at DORIS
LEP	From combination of all 4 LEP experiments: ALEPH, DELPHI, L3, OPAL
LEPS	Low-Energy Pion Spectrometer at the Paul Scherrer Institute
LGW	Lead Glass Wall collaboration at SPEAR/SLAC
LHC	Combined analysis of LHC experiments
LHCB	LHCb detector at CERN LHC
L+P	Multichannel L + P model fit
LSD	Mont Blanc liquid scintillator detector
LSND	Liquid Scintillator Neutrino Detector
LSW	Light Shining through a Wall
LUX	Large Underground Xenon experiment at SURF
MAC	MAC detector at PEP/SLAC
MAJD	Majorana Demonstrator experiment at SURF
MBNE	Fermilab MiniBooNE neutrino experiment
MBR	Molecular beam resonance technique
MCBN	Fermilab MicroBooNE neutrino experiment
MCRO	MACRO detector in Gran Sasso
MD1	Magnetic detector at VEPP-4, Novosibirsk
MDRP	Millikan drop measurement
MEG	Muon to electron conversion detector at PSI
MGFL	MAGIC and Fermi-LAT Collaborations
MGIC	MAGIC Telescopes gamma-ray observatory
MICA	Underground mica deposits
MICR	MICROSCOPE satellite test of weak equivalence principle
MINS	Fermilab MINOS experiment
MIRA	MIRABELLE Liquid-hydrogen bubble chamber
MLEV	Magnetic levitation
MLS	Modified Laurent Series
MMS	Missing mass spectrometer
MOED	MoEDAL magnetic monopoles search experiment at LHC
MPS	Multiparticle spectrometer at BNL
MPS2	Multiparticle spectrometer upgrade at BNL
MPSF	Multiparticle spectrometer at Fermilab
MPWA	Model-dependent partial-wave analysis
MRK1	SLAC Mark-I detector
MRK2	SLAC Mark-II detector
MRK3	SLAC Mark-III detector
MRKJ	Mark-J detector at DESY
MRS	Magnetic resonance spectrometer
MUG2	Muon (g-2)
MWPC	Multi-Wire Proportional Chamber
NA14	CERN NA14
NA31	CERN NA31 Spectrometer-Calorimeter
NA32	CERN NA32 Spectrometer
NA48	CERN NA48 Collaboration
NA49	CERN NA49 Collaboration
NA60	CERN NA60 Collaboration
NA62	CERN NA62 Experiment
NA64	CERN SPS NA64 Experiment
NAGE	NEWAGE, New generation WIMP-search experiment with advanced gaseous tracking
NAIA	NAIAD (NaI Advanced Detector) dark matter search experiment
ND	NaI detector at VEPP-2M, Novosibirsk
NEOS	NEOS Collaboration
NEWS	NEWS-G direct dark matter search at LSM

NICE Serpukhov nonmagnetic precision spectrometer
NMR Nuclear magnetic resonance
NOMD NOMAD Collaboration, CERN SPS
NOVA NOvA experiment with Fermilab's NuMI neutrino beam
NTEV NuTeV Collab. at Fermilab
nTRV neutron Time-Reversal Violation
NUSX Mont Blanc NUSEX underground detector
OBLX OBELIX detector at LEAR
OKA OKA collaboration at U70 accelerator in Protvino, Russia
OLYA Detector at VEPP-2M and VEPP-4, Novosibirsk
OMEG CERN OMEGA spectrometer
OPAL OPAL detector at LEP
OPER OPERA experiment with emulsion tracking at Gran Sasso
OSPK Optical spark chamber
PIBE The PIBETA detector at the Paul Scherrer Institute (PSI), Switzerland.
PICA PICASSO dark matter search experiment
PICO PICO bubble chamber experiment in SNOLAB underground laboratory
PIE3 πE3 beam-line of Paul Scherrer Institute
PLAS Plastic detector
PLUT DESY PLUTO detector
PMLA PAMELA space spectrometer on Resurs-DK1 satellite
PNDX PandaX dual-phase liquid xenon dark matter experiment at Jin-Ping
PPTA Parkes Pulsar Timing Array
PRMX The PRIMEX detector in Hall B at TJNAF
PWA Partial-wave analysis
QUAX QUAX axion search experiment
RADE CAST-RADES haloscope search for axions.
RDK2 NIST rare radioactive decay experiment
REDE Resonance depolarization
RENO RENO Collaboration
RICE Radio Ice Cherenkov Experiment
RVUE Review of previous data
SAGE US - Russian Gallium Experiment
SCDM SuperCDMS experiment at Soudan Underground Lab.
SELX FNAL SELEX Collab.
SENS Sub-Electron-Noise Skipper CCD Experimental Instrument (SENSEI)
SFM CERN split-field magnet
SHF SLAC Hybrid Facility Photon Collaboration
SHFT Search for Halo Axions with Ferromagnetic Toroids
SHUK SHUKET: search for U(1) dark matter with an electromagnetic telescope
SIGM Serpukhov CERN-IHEP magnetic spectrometer (SIGMA)
SILI Silicon detector
SIMP SIMPLE, dark matter detector at Laboratori Nazionali del Sud
SKAM Super-Kamiokande Collab.
SLAX Solar Axion Experiment in Canfranc Underground Laboratory
SLD SLC Large Detector for $e^+ e^-$ colliding beams at SLAC
SLIC ADMX SLIC (Superconducting LC Circuit Investigating Cold Axions)
SMPL SIMPLE, Superheated Instrument for Massive ParticLe Experiments
SND Novosibirisk Spherical neutral detector at VEPP-2M
SNDR SINDRUM spectrometer at PSI
SNO SNO Collaboration (Sudbury Neutrino Observatory)
SNO+ SNO+ Collaboration (Sudbury Neutrino Observatory)
SOU2 Soudan 2 underground detector
SOUD Soudan underground detector
SPEC Spectrometer
SPED From maximum of speed plot or resonant amplitude
SPHR Bonn SAPHIR Collab.
SPNX SPHINX spectrometer at IHEP accelerator
SPRK Spark chamber
SQID SQUID device
STRC Streamer chamber
SVD2 SVD-2 experiment at IHEP, Protvino
T2K T2K Collaboration
TASS DESY TASSO detector
TEVA Combined analysis of CDF and DØ experiments
TEXO TEXONO Collab., ultra low energy Ge detector at Kuo-Sheng Laboratory
THEO Theoretical or heavily model-dependent result
TNF TNF-IHEP facility at 70 GeV IHEP accelerator
TOF Time-of-flight
TOPZ TOPAZ detector at KEK-TRISTAN
TPC TPC detector at PEP/SLAC
TPS Tagged photon spectrometer at Fermilab
TRAP Penning trap
TWST TWIST spectrometer at TRIUMF
UA1 UA1 detector at CERN
UA2 UA2 detector at CERN
UA5 UA5 detector at CERN
UCNA UCNA collaboration using polarizeed ultracold neutrons at LANSCE
UKDM UK Dark Matter Collab.
VES Vertex Spectrometer Facility at 70 GeV IHEP accelerator
VLBI Very Long Baseline Interferometer
VNS VENUS detector at KEK-TRISTAN
VRTS Very Energetic Radiation Imaging Telescope Array System (VERITAS)
WA75 CERN WA75 experiment
WA82 CERN WA82 experiment
WA89 CERN WA89 experiment
WARP Liquid argon detector for CDM searches at Gran Sasso
WASA WASA detector at CELSIUS, Uppsala and at COSY, Juelich
WDMX WISP Dark Matter eXperiment (WISPDMX) for direct hidden photon search
WIRE Wire chamber
X100 XENON100 dark matter search experiment at Gran Sasso National Laboratory
XE10 XENON10 experiment at Gran Sasso National Laboratory
XE1T XENON1T dark matter search experiment at Gran Sasso National Laboratory
XEBC Xenon bubble chamber
XMAS XMASS, liquid xenon scintillation detector at Kamioka Observatory
YUKA Graviton mass measurement based on Yukawa potential
ZEP2 ZEPLIN-II dark matter detector
ZEP3 ZEPLIN-III dark matter detector at Palmer Underground Lab.
ZEPL ZEPLIN-I galactic dark matter detector
ZEUS ZEUS detector at DESY/HERA

Conferences

Conferences are generally referred to by the location at which they were held (e.g., HAMBURG, TORONTO, CORNELL, BRIGHTON, etc.).

GAUGE AND HIGGS BOSONS

γ (photon)

$I(J^{PC}) = 0,1(1^{--})$

γ MASS

Results prior to 2008 are critiqued in GOLDHABER 10. All experimental results published prior to 2005 are summarized in detail by TU 05.

The following conversions are useful: 1 eV = 1.783×10^{-33} g = 1.957×10^{-6} m_e; $\lambda\!\!\!^{-}_C = (1.973 \times 10^{-7}$ m)$\times$(1 eV/m_γ).

VALUE (eV)	CL%	DOCUMENT ID		COMMENT

[1] RYUTOV 07 extends the method of RYUTOV 97 to the radius of Pluto's orbit.

[2] BONETTI 17 uses frequency-dependent time delays of repeating FRB with well-determined redshift, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit 2.2×10^{-14} eV.

[3] BONETTI 16 uses frequency-dependent time delays of FRB, assuming the DM is caused by expected dispersion in IGM. There are several uncertainties, leading to mass limit 1.8×10^{-14} eV, if indeed the FRB is at the initially reported redshift.

[4] RETINO 16 looks for deviations from Ampere's law in the solar wind, using Cluster four spacecraft data. Authors quote a range of limits from 1.9×10^{-15} eV to 7.9×10^{-14} eV depending on the assumptions of the vector potential from the interplanetary magnetic field.

[5] EGOROV 14 studies chromatic dispersion of lensed quasar positions ("gravitational rainbows") that could be produced by any of several mechanisms, among them via photon mass. Limit not competitive but obtained on cosmological distance scales.

[6] ACCIOLY 10 limits come from possible alterations of anomalous magnetic moment of electron and gravitational deflection of electromagnetic radiation. Reported limits are not "claimed" by the authors and in any case are not competitive.

[7] When trying to measure m one must distinguish between measurements performed on large and small scales. If the photon acquires mass by the Higgs mechanism, the large-scale behavior of the photon might be effectively Maxwellian. If, on the other hand, one postulates the Proca regime for all scales, the very existence of the galactic field implies $m < 10^{-26}$ eV, as correctly calculated by YAMAGUCHI 59 and CHIBISOV 76.

[8] TU 06 continues the work of LUO 03, with extended LAKES 98 method, reporting the improved limit $\mu^2 A = (0.7 \pm 1.7) \times 10^{-13}$ T/m if $A = 0.2$ μG out to 4×10^{22} m. Reported result $\mu = (0.9 \pm 1.5) \times 10^{-52}$ g reduces to the frequentist mass limit 1.2×10^{-19} eV (FELDMAN 98).

[9] FULLEKRUG 04 adopted KROLL 71A method with newer and better Schumann resonance data. Result questionable because assumed frequency shift with photon mass is assumed to be linear. It is quadratic according to theorem by GOLDHABER 71B, KROLL 71, and PARK 71.

[10] LUO 03 extends LAKES 98 technique to set a limit on $\mu^2 A$, where μ^{-1} is the Compton wavelength $\lambda\!\!\!^{-}_C$ of the massive photon and A is the ambient vector potential. The important departure is that the apparatus rotates, removing sensitivity to the direction of A. They take $A = 10^{12}$ Tm, due to "cluster level fields." But see comment of GOLDHABER 03 and reply by LUO 03B.

[11] LAKES 98 reports limits on torque on a toroid Cavendish balance, obtaining a limit on $\mu^2 A < 2 \times 10^{-9}$ Tm/m^2 via the Maxwell-Proca equations, where μ^{-1} is the characteristic length associated with the photon mass and A is the ambient vector potential in the Lorentz gauge. Assuming $A \approx 1 \times 10^{12}$ Tm due to cluster fields he obtains $\mu^{-1} > 2 \times 10^{10}$ m, corresponding to $\mu < 1 \times 10^{-17}$ eV. A more conservative limit, using $A \approx (1$ μG)$\times$(600 pc) based on the galactic field, is $\mu^{-1} > 1 \times 10^{9}$ m or $\mu < 2 \times 10^{-16}$ eV.

[12] RYUTOV 97 uses a magnetohydrodynamics argument concerning survival of the Sun's field to the radius of the Earth's orbit. "To reconcile observations to theory, one has to reduce [the photon mass] by approximately an order of magnitude compared with" per DAVIS 75. "Secure limit, best by this method" (per GOLDHABER 10).

[13] FISCHBACH 94 analysis is based on terrestrial magnetic fields; approach analogous to DAVIS 75. Similar result based on a much smaller planet probably follows from more precise B field mapping. "Secure limit, best by this method" (per GOLDHABER 10).

[14] CHERNIKOV 92, motivated by possibility that photon exhibits mass only below some unknown critical temperature, searches for departure from Ampere's Law at 1.24 K. See also RYAN 85.

[15] RYAN 85, motivated by possibility that photon exhibits mass only below some unknown critical temperature, sets mass limit at $< (1.5 \pm 1.4) \times 10^{-42}$ g based on Coulomb's Law departure limit at 1.36 K. We report the result as frequentist 90% CL (FELDMAN 98).

[16] CHIBISOV 76 depends in critical way on assumptions such as applicability of virial theorem. Some of the arguments given only in unpublished references.

[17] DAVIS 75 analysis of Pioneer-10 data on Jupiter's magnetic field. "Secure limit, best by this method" (per GOLDHABER 10).

[18] FRANKEN 71 method is of dubious validity (KROLL 71A, JACKSON 99, GOLDHABER 10, and references therein).

[19] KROLL 71A used low frequency Schumann resonances in cavity between the conducting earth and resistive ionosphere, overcoming objections to resonant-cavity methods (JACKSON 99, GOLDHABER 10, and references therein). "Secure limit, best by this method" (per GOLDHABER 10).

[20] WILLIAMS 71 is landmark test of Coulomb's law. "Secure limit, best by this method" (per GOLDHABER 10).

γ CHARGE

OKUN 06 has argued that schemes in which all photons are charged are inconsistent. He says that if a neutral photon is also admitted to avoid this problem, then other problems emerge, such as those connected with the emission and absorption of charged photons by charged particles. He concludes that in the absence of a self-consistent phenomenological basis, interpretation of experimental data is at best difficult.

$<2 \times 10^{-32}$		COCCONI	88	TOF	Pulsar $f_1 - f_2$ TOF

[1] ALTSCHUL 07B looks for Aharonov-Bohm phase shift in addition to geometric phase shift in radio interference fringes (VSOP mission).

[2] CAPRINI 05 uses isotropy of the cosmic microwave background to place stringent limits on possible charge asymmetry of the Universe. Charge limits are set on the photon, neutrino, and dark matter particles. Valid if charge asymmetries produced by different particles are not anticorrelated.

[3] KOBYCHEV 05 considers a variety of observable effects of photon charge for extragalactic compact radio sources. Best limits if source observed through a foreground cluster of galaxies.

[4] SEMERTZIDIS 03 reports the first laboratory limit on the photon charge in the last 30 years. Straightforward improvements in the apparatus could attain a sensitivity of 10^{-20} e.

[5] SIVARAM 95 requires that CMB photon charge density not overwhelm gravity. Result scales as $\Omega_M h^2$.

[6] RAFFELT 94 notes that COCCONI 88 neglects the fact that the time delay due to dispersion by free electrons in the interstellar medium has the same photon energy dependence as that due to bending of a charged photon in the magnetic field. His limit is based on the assumption that the entire observed dispersion is due to photon charge. It is a factor of 200 less stringent than the COCCONI 88 limit.

[7] See COCCONI 92 for less stringent limits in other frequency ranges. Also see RAFFELT 94 note.

graviton

$J = 2$

graviton MASS

It is likely that the graviton is massless. More than fifty years ago Van Dam and Veltman (VANDAM 70), Iwasaki (IWASAKI 70), and Zakharov (ZAKHAROV 70) almost simultaneously showed that in the linear approximation a theory with a finite graviton mass does not approach GR as the mass approaches zero. Attempts have been made to evade this "vDVZ discontinuity" by invoking modified gravity or nonlinear theory by De Rahm (DE-RHAM 17) and others. More recently, the analysis of gravitational wave dispersion has led to bounds that are largely independent of the underlying model, even if not the strongest. We quote the best of these as our best limit.

Experimental limits have been set based on a Yukawa potential (YUKA), dispersion relation (DISP), or other modified gravity theories (MGRV).

The following conversions are useful: 1 eV $= 1.783 \times 10^{-33}$ g $= 1.957 \times 10^{-6}$ m_e; $\lambda\!\!\!^{-}_C = (1.973 \times 10^{-7}\ \text{m}) \times (1\ \text{eV}/m_g)$.

[1] ABBOTT 21 assumed modified gravitational-wave dispersion to establish a limit on graviton mass, using LIGO-Virgo O1-O3a binary black hole (BBH) events.

[2] BERNUS 20 use the latest solution of the ephemeris INPOP (19a) in order to improve the constraint in BERNUS 19 on the existence of a Yukawa suppression to the Newtonian potential, generically associated to a gravitons mass.

[3] SHAO 20 sets limit, 95% CL, based on non-observation of excess gravitational radiation in 14 well-timed binary pulsars in the context of the cubic Galileon model.

[4] ABBOTT 19, ABBOTT 17, and ABBOTT 16 assumed modified gravitational waves dispersion to establish limits on graviton mass.

[5] BERNUS 19 use the planetary ephemeris INPOP 17b to constraint the existence of a Yukawa suppression to the Newtonian potential, generically associated to a gravitons mass.

[6] MIAO 19 90% CL limit is based on orbital period decay rates of 9 binary pulsars using a Bayesian prior uniform in graviton mass. Limit becomes $< 5.2 \times 10^{-21}$ eV for a prior uniform in $\ln(m_g)$.

[7] DESAI 18 limit based on dynamical mass models of galaxy cluster Abell 1689.

[8] GUPTA 18 obtains graviton mass limits using stacked clusters from 3 disparate surveys.

[9] RANA 18 limit, 68% CL, obtained using weak lensing mass profiles out to the radius at which the cluster density falls to 200 times the critical density of the Universe. Limit is based on the fractional change between Newtonian and Yukawa accelerations for the 50 most massive galaxy clusters in the Local Cluster Substructure Survey. Limits for other CL's and other density cuts are also given.

[10] RANA 18 limit, 68% CL, obtained using mass measurements via the SZ effect out to the radius at which the cluster density falls to 500 times the critical density of the Universe for 182 optically confirmed galaxy clusters in an Altacama Cosmology Telescope survey. Limits for other CL's and other density cuts are also given.

[11] WILL 18 limit from perihelion advances of the planets, notably Earth, Mars, and Saturn. Alternate analysis yields $< 6 \times 10^{-24}$.

[12] ZAKHAROV 16 constrains range of Yukawa gravity interaction from S2 star orbit about black hole at Galactic center. The limit is $< 2.9 \times 10^{-21}$ eV for $\delta = 100$.

[13] BRITO 13 explore massive graviton (spin-2) fluctuations around rotating black holes.

[14] GRUZINOV 05 uses the DGP model (DVALI 00) showing that non-perturbative effects restore continuity with Einstein's equations as the gravition mass approaches zero, then bases his limit on Solar System observations.

[15] CHOUDHURY 04 concludes from a study of weak-lensing data that masses heavier than about the inverse of 100 Mpc seem to be ruled out if the gravitation field has the Yukawa form.

[16] GERSHTEIN 04 use non-Einstein field relativistic theory of gravity (RTG), with a massive graviton, to obtain the 95% CL mass limit implied by the value of $\Omega_{tot} = 1.02 \pm 0.02$ current at the time of publication.

[17] FINN 02 analyze the orbital decay rates of PSR B1913+16 and PSR B1534+12 with a possible graviton mass as a parameter. The combined frequentist mass limit is at 90%CL.

[18] As of 2020, limits on dP/dt are now about 0.1% (see T. Damour, "Experimental tests of gravitational theory," in this *Review*).

[19] GOLDHABER 74 establish this limit considering the binding of galactic clusters, corrected to Planck $h_0 = 0.67$.

Mass and Width of the W Boson

W MASS

The W-mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average W mass based on published results from ALEPH, DELPHI, L3, and OPAL is 80.376 ± 0.033 GeV [SCHAEL 13A]. The combined Tevatron data from CDF and D0 yields an average W mass of 80.387 ± 0016 GeV [AALTONEN 13N]. Assuming a common systematic error of 9 MeV due to PDF uncertainty, the combined LHC data from ATLAS [AABOUD 18J] and LHCb [AAIJ 22C] yields an average W mass of 80.366 ± 0.017 GeV [J. Erler and A. Freitas, "Electroweak Model and Constraints on New Physics" review, PDG 22]. Assuming 7 MeV as the common systematic uncertainty between the LHC

and Tevatron results, the average W mass from the two hadron colliders is estimated to be 80.377 ± 0.013 GeV. Combining this result with the LEP-2 value assuming no correlations, the world average W mass of 80.377 ± 0.012 GeV is obtained [Ibid]; OUR FIT quotes this value for the W mass.

In April 2022, after the cut-off of results for this review, the CDF collaboration published a determination of the W mass based on their full Run-2 dataset of 8.8 fb^{-1} [AALTONEN 22], with much reduced uncertainty: 80433.5 ± 9.4 MeV. This new CDF result, which includes the data of their previous result [AALTONEN 12E] and thus supersedes it, is of higher precision than our world average quoted above. However, the two determinations disagree significantly. More information is given in M. Grunewald and A. Gurtu, "Mass and Width of the W Boson" review [PDG 22].

[1] AAIJ 22C analyse W production in the muon decay channel, with the transverse momentum of the muon required to be between 28 and 52 GeV. Analysing the distribution of the muon charge divided by the muon transverse momentum of approximately 2.4 million selected W candidates, a value of M_W = 80354 ± 23(stat.)±10(exp.)±17(theo.)±9(PDF) MeV is obtained; we combine the three systematic uncertainties in quadrature.

[2] AABOUD 18J select 4.61M $W^+ \to \mu^+\nu_\mu$, 3.40M $W^+ \to e^+\nu_e$, 3.23M $W^- \to \mu^-\overline{\nu}_\mu$ and 2.49M $W^- \to e^-\overline{\nu}_e$ events in 4.6 fb^{-1} pp data at 7 TeV. The W mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations. The systematic error includes 0.011 GeV experimental and 0.014 GeV modelling uncertainties.

[3] AALTONEN 12E select 470k $W \to e\nu$ decays and 625k $W \to \mu\nu$ decays in 2.2 fb^{-1} of Run-II data. The mass is determined using the transverse mass, transverse lepton momentum and transverse missing energy distributions, accounting for correlations. This result supersedes AALTONEN 07F. AALTONEN 14D gives more details on the procedures followed by the authors.

[4] Combination of results from ABAZOV 12F and ABAZOV 09AB as quoted in ABAZOV 12F.

[5] ABDALLAH 08A use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu$ and $W^+W^- \to q\overline{q}q\overline{q}$ events for energies 172 GeV and above. The W mass was also extracted from the dependence of the WW cross section close to the production threshold and combined appropriately to obtain the final result. The systematic error includes ±0.025 GeV due to final state interactions and ±0.009 GeV due to LEP energy uncertainty.

[6] ABBIENDI 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The result quoted here is obtained combining this mass value with the results using $W^+W^- \to \ell\nu_\ell\ell'\nu_{\ell'}$ events in the energy range 183–207 GeV (ABBIENDI 03C) and the dependence of the WW production cross-section on m_W at threshold. The systematic error includes ±0.009 GeV due to the uncertainty on the LEP beam energy.

[7] ACHARD 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this mass value with the results obtained from a direct W mass reconstruction at 172 and 183 GeV and with those from the dependence of the WW production cross-section on m_W at 161 and 172 GeV (ACCIARRI 99).

[8] SCHAEL 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 183–209 GeV. The result quoted here is obtained combining this mass value with those obtained from the dependence of the W pair production cross-section on m_W at 161 and 172 GeV (BARATE 97 and BARATE 97S respectively). The systematic error includes ±0.009 GeV due to possible effects of final state interactions in the $q\overline{q}q\overline{q}$ channel and ±0.009 GeV due to the uncertainty on the LEP beam energy.

[9] ABAZOV 02D improve the measurement of the W-boson mass including $W \to e\nu_e$ events in which the electron is close to a boundary of a central electromagnetic calorimeter module. Properly combining the results obtained by fitting $m_T(W)$, $p_T(e)$, and $p_T(\nu)$, this sample provides a mass value of 80.574 ± 0.405 GeV. The value reported here is a combination of this measurement with all previous DØ W-boson mass measurements.

[10] AFFOLDER 01E fit the transverse mass spectrum of 30115 $W \to e\nu_e$ events (M_W= 80.473 ± 0.065 ± 0.092 GeV) and of 14740 $W \to \mu\nu_\mu$ events (M_W= 80.465 ± 0.100 ± 0.103 GeV) obtained in the run IB (1994-95). Combining the electron and muon results, accounting for correlated uncertainties, yields M_W= 80.470 ± 0.089 GeV. They combine this value with their measurement of ABE 95P reported in run IA (1992-93) to obtain the quoted value.

[11] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.

[12] ABAZOV 12F select 1677k $W \to e\nu$ decays in 4.3 fb^{-1} of Run-II data. The mass is determined using the transverse mass and transverse lepton momentum distributions, accounting for correlations.

[13] ABAZOV 09AB study the transverse mass, transverse electron momentum, and transverse missing energy in a sample of 0.5 million $W \to e\nu$ decays selected in Run-II data. The quoted result combines all three methods, accounting for correlations.

[14] AALTONEN 07F obtain high purity $W \to e\nu_e$ and $W \to \mu\nu_\mu$ candidate samples totaling 63,964 and 51,128 events respectively. The W mass value quoted above is derived by simultaneously fitting the transverse mass and the lepton, and neutrino p_T distributions.

[15] AKTAS 06 fit the Q^2 dependence ($300 < Q^2 < 30{,}000$ GeV^2) of the charged-current differential cross section with a propagator mass. The first error is experimental and the second corresponds to uncertainties due to input parameters and model assumptions.

[16] CHEKANOV 02C fit the Q^2 dependence ($200 < Q^2 < 60000$ GeV^2) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

[17] BREITWEG 00D fit the Q^2 dependence ($200 < Q^2 < 22500$ GeV^2) of the charged-current differential cross sections with a propagator mass fit. The last error is due to the uncertainty on the probability density functions.

[18] ALITTI 92B result has two contributions to the systematic error (±0.83); one (±0.81) cancels in m_W/m_Z and one (±0.17) is noncancelling. These were added in quadrature. We choose the ALITTI 92B value without using the LEP m_Z value, because we perform our own combined fit.

[19] There are two contributions to the systematic error (±0.84): one (±0.81) which cancels in m_W/m_Z and one (±0.21) which is non-cancelling. These were added in quadrature.

[20] ABE 89I systematic error dominated by the uncertainty in the absolute energy scale.

[21] ALBAJAR 89 result is from a total sample of 299 $W \to e\nu$ events.

[22] ALBAJAR 89 result is from a total sample of 67 $W \to \mu\nu$ events.

[23] ALBAJAR 89 result is from $W \to \tau\nu$ events.

−0.029±0.013±0.025	13.7M	[1] AABOUD	18J	ATLS	E_{cm}^{pp} = 7 TeV
−0.19 ±0.58	1722	ABE	90G	CDF	$E_{cm}^{p\overline{p}}$= 1.8 TeV

[1] AABOUD 18J select 4.61M $W^+ \to \mu^+\nu_\mu$, 3.40M $W^+ \to e^+\nu_e$, 3.23M $W^- \to \mu^-\overline{\nu}_\mu$ and 2.49M $W^- \to e^-\overline{\nu}_e$ events in 4.6 fb^{-1} pp data at 7 TeV. The W mass is determined using the transverse mass and transverse lepton momentum distributions,

accounting for correlations. The systematic error includes 0.007 GeV experimental and 0.024 GeV modelling uncertainties.

W WIDTH

The W width listed here corresponds to the width parameter in a Breit-Wigner distribution with mass-dependent width. To obtain the world average, common systematic uncertainties between experiments are properly taken into account. The LEP-2 average W width based on published results is 2.195 ± 0.083 GeV [SCHAEL 13A]. The combined Tevatron data yields an average W width of 2.046±0.049 GeV [FERMILAB-TM-2460-E].

OUR FIT uses these average LEP and Tevatron width values and combines them assuming no correlations.

[1] ABAZOV 09AK obtain this result fitting the high-end tail (100-200 GeV) of the transverse mass spectrum in $W \to e\nu$ decays.

[2] AALTONEN 08B obtain this result fitting the high-end tail (90–200 GeV) of the transverse mass spectrum in semileptonic $W \to e\nu_e$ and $W \to \mu\nu_\mu$ decays.

[3] ABDALLAH 08A use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.065 GeV due to final state interactions.

[4] ABBIENDI 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.003 GeV due to the uncertainty on the LEP beam energy.

[5] ACHARD 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events in the C.M. energy range 189–209 GeV. The result quoted here is obtained combining this value of the width with the result obtained from a direct W mass reconstruction at 172 and 183 GeV (ACCIARRI 99).

[6] SCHAEL 06 use direct reconstruction of the kinematics of $W^+W^- \to q\overline{q}\ell\nu_\ell$ and $W^+W^- \to q\overline{q}q\overline{q}$ events. The systematic error includes ±0.05 GeV due to possible effects of final state interactions in the $q\overline{q}q\overline{q}$ channel and ±0.01 GeV due to the uncertainty on the LEP beam energy.

[7] ABAZOV 02E obtain this result fitting the high-end tail (90–200 GeV) of the transverse-mass spectrum in semileptonic $W \to e\nu_e$ decays.

[8] AFFOLDER 00M fit the high transverse mass (100–200 GeV) $W \to e\nu_e$ and $W \to \mu\nu_\mu$ events to obtain $\Gamma(W)$= 2.04 ± 0.11(stat)±0.09(syst) GeV. This is combined with the earlier CDF measurement (ABE 95C) to obtain the quoted result.

[9] ABBOTT 00B measure R = 10.43 ± 0.27 for the $W \to e\nu_e$ decay channel. They use the SM theoretical predictions for $\sigma(W)/\sigma(Z)$ and $\Gamma(W \to e\nu_e)$ and the world average for $B(Z \to ee)$. The value quoted here is obtained combining this result (2.169 ± 0.070 GeV) with that of ABBOTT 99H.

[10] ABE 95W measured R = 10.90 ± 0.32 ± 0.29. They use m_W=80.23 ± 0.18 GeV, $\sigma(W)/\sigma(Z)$ = 3.35 ± 0.03, $\Gamma(W \to e\nu)$ = 225.9 ± 0.9 MeV, $\Gamma(Z \to e^+e^-)$ = 83.98 ± 0.18 MeV, and $\Gamma(Z)$ = 2.4969 ± 0.0038 GeV.

[11] ALITTI 92 measured $R = 10.4^{+0.7}_{-0.6} \pm 0.3$. The values of $\sigma(Z)$ and $\sigma(W)$ come from $O(\alpha_s^2)$ calculations using m_W = 80.14 ± 0.27 GeV, and m_Z = 91.175 ± 0.021 GeV along with the corresponding value of $\sin^2\theta_W$ = 0.2274. They use $\sigma(W)/\sigma(Z)$ = 3.26 ± 0.07 ± 0.05 and $\Gamma(Z)$ = 2.487 ± 0.010 GeV.

[12] ALBAJAR 91 measured $R = 9.5^{+1.1}_{-1.0}$ (stat. + syst.). $\sigma(W)/\sigma(Z)$ is calculated in QCD at the parton level using m_W = 80.18 ± 0.28 GeV and m_Z = 91.172 ± 0.031 GeV along with $\sin^2\theta_W$ = 0.2322 ± 0.0014. They use $\sigma(W)/\sigma(Z)$ = 3.23 ± 0.05 and $\Gamma(Z)$ = 2.498 ± 0.020 GeV. This measurement is obtained combining both the electron and muon channels.

W^+ DECAY MODES

W^- modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)		Confidence level
Γ_1	$\ell^+\nu$	[a]	(10.86± 0.09) %		
Γ_2	$e^+\nu$		(10.71± 0.16) %

[a] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[b] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

W PARTIAL WIDTHS

Γ(invisible) Γ10

This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

VALUE (MeV)	DOCUMENT ID		TECN	COMMENT
$\mathbf{30^{+52}_{-48} \pm 33}$	[1] BARATE	99I	ALEP	E_{cm}^{ee}= 161+172+183 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[2] BARATE	99L	ALEP	E_{cm}^{ee}= 161+172+183 GeV

[1] BARATE 99I measure this quantity using the dependence of the total cross section σ_{WW} upon a change in the total width. The fit is performed to the WW measured cross sections at 161, 172, and 183 GeV. This partial width is < 139 MeV at 95%CL.

[2] BARATE 99L use W-pair production to search for effectively invisible W decays, tagging with the decay of the other W boson to Standard Model particles. The partial width for effectively invisible decay is < 27 MeV at 95%CL.

W BRANCHING RATIOS

Overall fits are performed to determine the branching ratios of the W boson. Averages on $W \to e\nu$, $W \to \mu\nu$, and $W \to \tau\nu$, and their correlations are obtained by combining results from the four LEP experiments properly taking into account the common systematic uncertainties and their correlations [SCHAEL 13A]. A first fit determines the three individual leptonic braching ratios $B(W \to e\nu)$, $B(W \to \mu\nu)$, and $B(W \to \tau\nu)$. This fit has a χ^2 = 6.3 for 9 degrees of freedom. The correlation coefficients between the branching fractions are 0.14 $(e-\mu)$, −0.20 $(e-\tau)$, −0.12 $(\mu-\tau)$. A second fit assumes lepton universality and determines the leptonic branching ratio $B(W \to \ell\nu)$ and the hadronic branching ratio is derived as $B(W \to \text{hadrons}) = 1 - 3\,B(W \to \ell\nu)$. This fit has a χ^2 = 15.4 for 11 degrees of freedom.

Γ(ℓ+ν)/Γtotal Γ1/Γ

ℓ indicates average over e, μ, and τ modes, not sum over modes.

[1] AABOUD 17Q make a precise determination of $W \to e\nu$ and $W \to \mu\nu$ production in the follwoing fiducial phase space: lepton pseudo-rapidity range $|\eta| < 2.5$, lepton and neutrino transverse momenta larger than 25 GeV each, and W transverse mass larger than 25 GeV. They determine the ratio of the W branching fractions $B(W \to e\nu)/B(W \to \mu\nu) = 0.9967 \pm 0.0004 \pm 0.0101 = 0.997 \pm 0.010$.

[2] AAIJ 16AJ make precise measurements of forward $W \to e\nu$ and $W \to \mu\nu$ production in proton-proton collisions at 8 TeV and determine the ratio of the W branching fractions $B(W \to e\nu)/B(W \to \mu\nu) = 1.020 \pm 0.002 \pm 0.019$.

[3] ABACHI 95D obtain this result from the measured $\sigma_W B(W \to \mu\nu) = 2.09 \pm 0.23 \pm 0.11$ nb and $\sigma_W B(W \to e\nu) = 2.36 \pm 0.07 \pm 0.13$ nb in which the first error is the combined statistical and systematic uncertainty, the second reflects the uncertainty in the luminosity.

[4] ABE 92I obtain $\sigma_W B(W \to \mu\nu) = 2.21 \pm 0.07 \pm 0.21$ and combine with ABE 91C $\sigma_W B((W \to e\nu))$ to give a ratio of the couplings from which we derive this measurement.

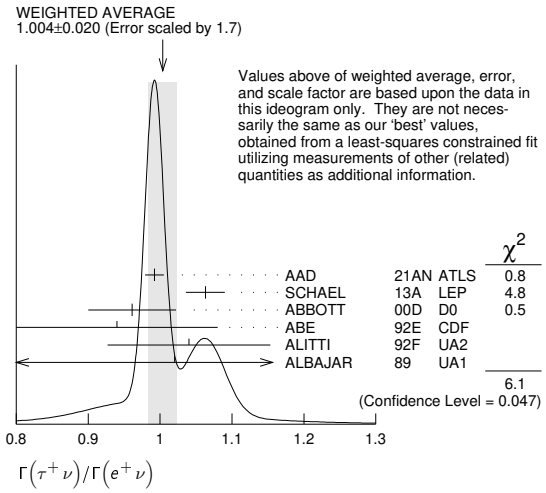
1.02 ±0.20 ±0.10	32	ALBAJAR	87	UA1	Repl. by ALBAJAR 89



[1] AAD 21AN study $t\overline{t}$ production, with the W bosons in top-quark decay decaying to electrons or taus, with the tau decaying further into a muon. Analyzing the muon impact parameter and its transverse momentum, the contributions from prompt muons (arising from W decay) and non-prompt muons (arising from tau decay) are separated, allowing a measurement of the ratio of the W branching fractions into taus and muons, $R(\tau/\mu) = 0.992 \pm 0.007 \pm 0.011$ where the first error is statistical and the second systematic.

[2] ABBOTT 00D measure $\sigma_W \times B(W \to \tau\nu_\tau) = 2.22 \pm 0.09 \pm 0.10 \pm 0.10$ nb. Using the ABBOTT 00B result $\sigma_W \times B(W \to e\nu_e) = 2.31 \pm 0.01 \pm 0.05 \pm 0.10$ nb, they quote the ratio of the couplings from which we derive this measurement.

[3] ABE 92E use two procedures for selecting $W \to \tau\nu_\tau$ events. The missing E_T trigger leads to $132 \pm 14 \pm 8$ events and the τ trigger to $47 \pm 9 \pm 4$ events. Proper statistical and systematic correlations are taken into account to arrive at $\sigma B(W \to \tau\nu) = 2.05 \pm 0.27$ nb. Combined with ABE 91C result on $\sigma B(W \to e\nu)$, ABE 92E quote a ratio of the couplings from which we derive this measurement.

[4] This measurement is derived by us from the ratio of the couplings of ALITTI 92F.

VALUE	DOCUMENT ID		TECN	COMMENT
19.39±0.08 OUR AVERAGE				
19.38±0.05±0.08	[1] ABBIENDI	06A	OPAL	E_{cm}^{ee} = 189–209 GeV
19.44±0.17	[2] ABREU,P	00F	DLPH	E_{cm}^{ee} = 183+189 GeV
19.3 ±0.3 ±0.3	[3] ABBIENDI	99N	OPAL	E_{cm}^{ee} = 183 GeV
19.23±0.74	[4] ABREU	98C	DLPH	E_{cm}^{ee} = 172 GeV

[1] ABBIENDI 06A measure $\langle N_{\text{charged}} \rangle = 38.74 \pm 0.12 \pm 0.26$ when both W bosons decay hadronically and $\langle N_{\text{charged}} \rangle = 19.39 \pm 0.11 \pm 0.09$ when one W boson decays semileptonically. The value quoted here is obtained under the assumption that there is no color reconnection between W bosons; the value is a weighted average taking into account correlations in the systematic uncertainties.

[2] ABREU,P 00F measure $\langle N_{\text{charged}} \rangle = 39.12 \pm 0.33 \pm 0.36$ and $38.11 \pm 0.57 \pm 0.44$ in the fully hadronic final states at 189 and 183 GeV respectively, and $\langle N_{\text{charged}} \rangle = 19.49 \pm 0.31 \pm 0.27$ and $19.78 \pm 0.49 \pm 0.43$ in the semileptonic final states. The value quoted is a weighted average without assuming any correlations.

[3] ABBIENDI 99N use the final states $W^+W^- \to q\overline{q}\ell\overline{\nu}_\ell$ to derive this value.

[4] ABREU 98C combine results from both the fully hadronic as well semileptonic WW final states after demonstrating that the W decay charged multiplicity is independent of the topology within errors.

TRIPLE GAUGE COUPLINGS (TGC'S)

Revised April 2017 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Fourteen independent couplings, seven each for ZWW and γWW, completely describe the VWW vertices within the most general framework of the electroweak Standard Model (SM) consistent with Lorentz invariance and U(1) gauge invariance. Of each of the seven TGCs, three conserve C and P individually, three violate CP, and one violates C and P individually while conserving CP. Assumption of C and P conservation and electromagnetic gauge invariance reduces the number of independent VWW couplings to five: one common set [1,2] is $(\kappa_\gamma, \kappa_Z, \lambda_\gamma, \lambda_Z, g_1^Z)$, where $\kappa_\gamma = \kappa_Z = g_1^Z = 1$ and $\lambda_\gamma = \lambda_Z = 0$ in the Standard Model at tree level. The parameters κ_Z and λ_Z are related to the other three due to constraints of gauge invariance as follows: $\kappa_Z = g_1^Z - (\kappa_\gamma - 1)\tan^2\theta_W$ and $\lambda_Z = \lambda_\gamma$, where θ_W is the weak mixing angle. The W magnetic dipole moment, μ_W, and the W electric quadrupole moment, q_W, are expressed as $\mu_W = e\,(1 + \kappa_\gamma + \lambda_\gamma)/2M_W$ and $q_W = -e\,(\kappa_\gamma - \lambda_\gamma)/M_W^2$.

Precision measurements of suitable observables at LEP1 has already led to an exploration of much of the TGC parameter space. At LEP2, the VWW coupling arises in W-pair production via s-channel exchange, or in single W production via the radiation of a virtual photon off the incident e^+ or e^-. At the Tevatron and the LHC, hard-photon bremsstrahlung off a produced W or Z signals the presence of a triple-gauge vertex. In order to extract the value of one TGC, the others are generally kept fixed to their SM values. While most analyses use the above gauge constraints in the extraction of TGCs, one analysis of W-pair events also determines the real and imaginary parts of all 14 couplings using unconstrained single-parameter fits [3]. The results are consistent. Some experiments have determined limits on the couplings under various non-LEP scenarios and assuming different values of the form factor Λ, where the coupling parameters are scaled by $1/(1+s/\Lambda^2)^2$. For practical reasons it is not possible to quote all such determinations in the listings. For that the individual papers may be consulted. Recently, EFT-inspired sets of couplings [4,5], such as $c_{WWW}/\Lambda^2, c_W/\Lambda^2, c_B/\Lambda^2$ which are linearly related to the couplings discussed above, are also determined by the LHC experiments.

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu, jjjj, jjX, \ell X$, at center-of-mass energies between 189–209 GeV at LEP2, where j = jet, ℓ = lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–W, and WW–pair production from 183 to 209 GeV. The result quoted here is derived from the WW–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from W^+W^- in all decay channels. Only CP-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.923 < g_1^Z < 1.054$.

[4] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained from the WW–pair production sample including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39 ± 0.17 (1.054 ± 0.058) million events. Analyzing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained: $0.971 < g_1^Z < 1.044$. Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes: $0.979 < g_1^Z < 1.034$.

[6] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9939 < g_1^Z < 1.0074$.

[7] SIRUNYAN 18BZ study $pp \to$ *Z jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton $>$ 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet $>$ 50/30 GeV respectively and dijet invariant mass $>$ 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained: $0.965 < g_1^Z < 1.042$.

[8] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.87 < g_1^Z < 1.12$.

[9] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.979 < g_1^Z < 1.024$.

[10] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.982 < g_1^Z < 1.035$.

[11] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.9913 < g_1^Z < 1.024$.

[12] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.984 < g_1^Z < 1.027$.

[13] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $0.981 < g_1^Z < 1.029$.

[14] AAD 14Y determine the electroweak Z-dijet cross section in 8 TeV pp collisions. $Z \to ee$ and $Z \to \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81–101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized p_T balance between the Z and the two jets is required to be < 0.15. This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $0.5 < g_1^Z < 1.26$ for a form factor value $\Lambda = \infty$.

[15] AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor $\Lambda =$ infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.961 < g_1^Z < 1.052$. Supersedes AAD 12AC.

[16] CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34. The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.905 \le g_1^Z \le 1.095$.

[17] AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $0.943 < g_1^Z < 1.093$. Supersedes AAD 12V.

[18] AALTONEN 12AC study WZ production in $p\overline{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $0.92 < g_1^Z < 1.20$ for a form factor of $\Lambda = 2$ TeV.

[19] ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $g_1^Z = 1.022^{+0.032}_{-0.030}$.

[20] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $0.944 < g_1^Z < 1.154$, for a form factor $\Lambda = 2$ TeV.

[21] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $0.76 < g_1^Z < 1.34$ for $\Lambda = 1.5$ TeV and $0.78 < g_1^Z < 1.30$ for $\Lambda = 2$ TeV.

[22] ABAZOV 09AD study the $p\overline{p} \to \ell\nu$ 2jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.88 < g_1^Z < 1.20$.

[23] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $0.86 < g_1^Z < 1.3$, for a form factor $\Lambda = 2$ TeV.

[24] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (qq)(\ell\nu)$, where $\ell = e$ or μ. Values of all other couplings are fixed to their standard model values.

[25] ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.86 < g_1^Z < 1.35$.

[26] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ (ℓ and ℓ' = e or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $0.51 < g_1^Z < 1.66$, fixing λ_Z and κ_Z to their Standard Model values.

[27] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^- and $We\nu_e$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.84 < g_1^Z < 1.13$.

[28] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.63 < g_1^Z < 1.57$, fixing λ_Z and κ_Z to their Standard Model values, and assuming Standard Model values for the $WW\gamma$ couplings.

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu$, $jjjj$, jjX, ℓX, at center-of-mass energies between 189–209 GeV at LEP2, where j = jet, ℓ = lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–W, and WW–pair production from 183 to 209 GeV. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from W^+W^- in all decay channels. Only *CP*-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $0.73 < \kappa_\gamma < 1.07$.

[4] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.939 < \kappa_\gamma < 1.064$.

[6] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $0.956 < \kappa_\gamma < 1.063$.

[7] CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be 3200 ± 325 and 4970 ± 543 respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $0.62 < \kappa_\gamma < 1.29$, assuming other parameters have SM values.

[8] AAD 13AN study $W\gamma$ production in pp collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of 1662 ± 262 (2538 ± 362) events. Analysing the photon p_T spectrum above 100 GeV yields a 95% C.L. limit of $0.59 < \kappa_\gamma < 1.46$. Supersedes AAD 12BX.

[9] CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high $\not{p}_T$. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34. The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $0.79 < k_\gamma < 1.22$.

[10] ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\kappa_\gamma = 1.048^{+0.106}_{-0.105}$.

[11] ABAZOV 11AC study $W\gamma$ production in $p\overline{p}$ collisions at 1.96 TeV, with the W decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon E_T spectrum above 15 GeV yields at 95% C.L. the result: $0.6 < \kappa_\gamma < 1.4$ for a formfactor $\Lambda = 2$ TeV.

[12] CHATRCHYAN 11M study $W\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data with the W decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 (228 ± 21) for the electron channel and 520 (277 ± 25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.11 < \kappa_\gamma < 2.04$.

[13] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $0.37 < \kappa_\gamma < 1.72$ for $\Lambda = 1.5$ TeV and $0.43 < \kappa_\gamma < 1.65$ for $\Lambda = 2$ TeV.

[14] AARON 09B study single-W production in ep collisions at 0.3 TeV C.M. energy. They select 53 $W \to e/\mu$ events with a standard model expectation of 54.1 ± 7.4 events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-3.7 < \kappa_\gamma < -1.5$ or $0.3 < \kappa_\gamma < 1.5$, where the ambiguity is due to the quadratic dependence of the cross section to the coupling parameter.

[15] ABAZOV 09AD study the $p\overline{p} \to \ell\nu$ 2jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $0.56 < \kappa_\gamma < 1.55$.

[16] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $0.46 < \kappa_\gamma < 1.83$, for a form factor $\Lambda = 2$ TeV.

[17] ABAZOV 08R use 0.7 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the W decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon E_T spectrum yields a 95% CL limit $0.49 < \kappa_\gamma < 1.51$ with other couplings fixed to their Standard Model values.

[18] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (qq)(\ell\nu)$, where $\ell = e$ or μ. Values of all other couplings are fixed to their standard model values.

[19] AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in WW and WZ production with the W decaying to an electron or muon and the Z to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $0.54 < \kappa_\gamma < 1.39$ for a form factor scale $\Lambda = 1.5$ TeV.

[20] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.05 < \kappa_\gamma < 2.29$, fixing $\lambda_\gamma = 0$. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.

[21] ABAZOV 05J perform a likelihood fit to the photon E_T spectrum of $W\gamma + X$ events, where the W decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $0.12 < \kappa_\gamma < 1.96$. In the fit λ_γ is kept fixed to its Standard Model value.

[22] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^-, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $0.87 < \kappa_\gamma < 1.68$.

[23] BREITWEG 00 search for W production in events with large hadronic p_T. For $p_T > 20$ GeV, the upper limit on the cross section gives the 95%CL limit $-3.7 < \kappa_\gamma < 2.5$ (for $\lambda_\gamma = 0$).

[24] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $0.75 < \kappa_\gamma < 1.39$.

λ_γ

[1] ABDALLAH 10 use data on the final states $e^+e^- \to jj\ell\nu$, $jjjj$, jjX, ℓX, at center-of-mass energies between 189–209 GeV at LEP2, where j = jet, ℓ = lepton, and X represents missing momentum. The fit is carried out keeping all other parameters fixed at their SM values.

[2] SCHAEL 05A study single–photon, single–W, and WW–pair production from 183 to 209 GeV. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[3] ABBIENDI 04D combine results from W^+W^- in all decay channels. Only CP-conserving couplings are considered and each parameter is determined from a single-parameter fit in which the other parameters assume their Standard Model values. The 95% confidence interval is $-0.13 < \lambda_\gamma < 0.01$.

[4] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained including data from 161 to 183 GeV, ACCIARRI 99Q. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[5] CHATRCHYAN 14AB measure $W\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. After background subtraction the number of $e\nu\gamma$ and $\mu\nu\gamma$ events is determined to be 3200 ± 325 and 4970 ± 543 respectively, compatible with expectations from the SM. This leads to a 95% CL limit of $-0.050 < \lambda_\gamma < 0.037$, assuming all other parameters have SM values.

[6] AAD 13AN study $W\gamma$ production in pp collisions. In events with no additional jet, 4449 (6578) W decays to electron (muon) are selected, with an expected background of 1662 ± 262 (2538 ± 362) events. Analysing the photon p_T spectrum above 100 GeV yields a 95% C.L. limit of $-0.065 < \lambda_\gamma < 0.061$. Supersedes AAD 12BX.

[7] ABAZOV 12AG combine new results with already published results on $W\gamma$, WW and WZ production in order to determine the couplings with increased precision, superseding ABAZOV 08R, ABAZOV 11AC, ABAZOV 09AJ, ABAZOV 09AD. The 68% C.L. result for a formfactor cutoff of $\Lambda = 2$ TeV is $\lambda_\gamma = 0.007^{+0.021}_{-0.022}$.

[8] ABAZOV 11AC study $W\gamma$ production in $p\overline{p}$ collisions at 1.96 TeV, with the W decay products containing an electron or a muon. They select 196 (363) events in the electron (muon) mode, with a SM expectation of 190 (372) events. A likelihood fit to the photon E_T spectrum above 15 GeV yields at 95% C.L. the result: $-0.08 < \lambda_\gamma < 0.07$ for a formfactor $\Lambda = 2$ TeV.

[9] CHATRCHYAN 11M study $W\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data with the W decaying to electron and muon. The total cross section is measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$. The number of candidate (background) events is 452 (228 ± 21) for the electron channel and 520 (277 ± 25) for the muon channel. Setting other couplings to their standard model value, they derive a 95% CL limit of $-0.18 < \lambda_\gamma < 0.17$.

[10] AARON 09B study single-W production in ep collisions at 0.3 TeV C.M. energy. They select 53 $W \to e/\mu$ events with a standard model expectation of 54.1 ± 7.4 events. Fitting the transverse momentum spectrum of the hadronic recoil system they obtain a 95% C.L. limit of $-2.5 < \lambda_\gamma < 2.5$.

[11] ABAZOV 09AD study the $p\overline{p} \to \ell\nu$ 2jet process arising in WW and WZ production. They select 12,473 (14,392) events in the electron (muon) channel with an expected di-boson signal of 436 (527) events. The results on the anomalous couplings are derived from an analysis of the p_T spectrum of the 2-jet system and quoted at 68% C.L. and for a form factor of 2 TeV. This measurement is not used for obtaining the mean as it is for a specific form factor. The 95% confidence interval is $-0.10 < \lambda_\gamma < 0.11$.

[12] ABAZOV 09AJ study the $p\overline{p} \to 2\ell 2\nu$ process arising in WW production. They select 100 events with an expected WW signal of 65 events. An analysis of the p_T spectrum of the two charged leptons leads to 95% C.L. limits of $-0.14 < \lambda_\gamma < 0.18$, for a form factor $\Lambda = 2$ TeV.

[13] ABAZOV 08R use 0.7 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV to select 263 $W\gamma + X$ events, of which 187 constitute signal, with the W decaying into an electron or a muon, which is required to be well separated from a photon with $E_T > 9$ GeV. A likelihood fit to the photon E_T spectrum yields a 95% CL limit $-0.12 < \lambda_\gamma < 0.13$ with other couplings fixed to their Standard Model values.

[14] ABDALLAH 08C determine this triple gauge coupling from the measurement of the spin density matrix elements in $e^+e^- \to W^+W^- \to (q\overline{q})(\ell\nu)$, where $\ell = e$ or μ. Values of all other couplings are fixed to their standard model values.

[15] AALTONEN 07L set limits on anomalous TGCs using the $p_T(W)$ distribution in WW and WZ production with the W decaying to an electron or muon and the Z to 2 jets. Setting other couplings to their standard model value, the 95% C.L. limits are $-0.18 < \lambda_\gamma < 0.17$ for a form factor scale $\Lambda = 1.5$ TeV.

[16] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 1$ TeV is $-0.97 < \lambda_\gamma < 1.04$, fixing κ_γ=1. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.

[17] ABAZOV 05J perform a likelihood fit to the photon E_T spectrum of $W\gamma$ + X events, where the W decays to an electron or muon which is required to be well separated from the photon. For $\Lambda = 2.0$ TeV the 95% CL limits are $-0.20 < \lambda_\gamma < 0.20$. In the fit κ_γ is kept fixed to its Standard Model value.

[18] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^-, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV. The 95% confidence interval is $-0.11 < \lambda_\gamma < 0.23$.

[19] BREITWEG 00 search for W production in events with large hadronic p_T. For $p_T > 20$ GeV, the upper limit on the cross section gives the 95%CL limit $-3.2 < \lambda_\gamma < 3.2$ for κ_γ fixed to its Standard Model value.

[20] ABBOTT 99I perform a simultaneous fit to the $W\gamma$, $WW \to$ dilepton, $WW/WZ \to e\nu jj$, $WW/WZ \to \mu\nu jj$, and $WZ \to$ trilepton data samples. For $\Lambda = 2.0$ TeV, the 95%CL limits are $-0.18 < \lambda_\gamma < 0.19$.

κ_Z

This coupling is *CP*-conserving (*C*- and *P*- separately conserving).

[1] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the WW–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[2] SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39 ± 0.17 (1.054 ± 0.058) million events. Analysing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained: $0.956 < \kappa_Z < 1.044$. Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes: $0.957 < \kappa_Z < 1.042$.

[3] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $0.9921 < \kappa_Z < 1.0082$.

[4] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $0.85 < \kappa_Z < 1.16$.

[5] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $0.79 < \kappa_Z < 1.25$.

[6] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.975 < \kappa_Z < 1.020$.

[7] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $0.81 < \kappa_Z < 1.30$.

[8] AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor Λ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $0.957 < \kappa_Z < 1.043$. Supersedes AAD 12AC.

[9] AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $0.63 < \kappa_Z < 1.57$. Supersedes AAD 12V.

[10] AALTONEN 12AC study WZ production in $p\overline{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $0.61 < \kappa_Z < 1.90$ for a form factor of $\Lambda = 2$ TeV.

[11] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $0.600 < \kappa_Z < 1.675$, for a form factor $\Lambda = 2$ TeV.

[12] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $0.55 < \kappa_Z < 1.55$, fixing λ_Z=0. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $0.68 < \kappa < 1.45$.

[13] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1$ TeV is $-1.0 < \kappa_Z < 3.4$, fixing λ_Z and g_1^Z to their Standard Model values.

λ_Z

This coupling is *CP*-conserving (*C*- and *P*- separately conserving).

[1] ACHARD 04D study WW–pair production, single–W production and single–photon production with missing energy from 189 to 209 GeV. The result quoted here is obtained using the WW–pair production sample. Each parameter is determined from a single–parameter fit in which the other parameters assume their Standard Model values.

[2] SIRUNYAN 20BA study electroweak production of a W boson in association with two jets, using W decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39 ± 0.17 (1.054 ± 0.058) million events. Analysing the transverse momentum distribution of the charged leptons from W decay, the following 95% C.L. limit is obtained: $-0.0088 < \lambda_Z < 0.0095$. Combining this result with that from the closely-related electroweak Z-jet-jet production SIRUNYAN 18BZ, the limit becomes: $-0.0071 < \lambda_Z < 0.0076$.

[3] SIRUNYAN 19CL study WW and WZ production in lepton + jet events, with one W boson decaying leptonically (electron or muon), and another W or Z boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the $WW(WZ)$ category, while in the muon channel 3,996 (3572) events are selected in the $WW(WZ)$ category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limit is obtained: $-0.0065 < \lambda_Z < 0.0066$.

[4] SIRUNYAN 18BZ study $pp \to Z$ *jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton > 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the Z mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet > 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the Z are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limit is obtained $-0.010 < \lambda_Z < 0.010$.

[5] AABOUD 17S analyze electroweak production of a W boson in association with two jets at high dijet invariant mass, with the W boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.053 < \lambda_Z < 0.042$.

[6] AABOUD 17U analyze production of WW or WZ boson pairs with one W boson decaying to electron or muon plus neutrino, and the other W or Z boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limit at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.013 < \lambda_Z < 0.013$.

[7] KHACHATRYAN 17O analyse WZ production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV, with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set a 95% C.L. limit of: $-0.018 < \lambda_Z < 0.016$.

[8] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limit is obtained: $-0.011 < \lambda_Z < 0.011$.

[9] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming the LEP formulation and setting the form-factor Λ to infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.019 < \lambda_Z < 0.019$.

[10] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limit is: $-0.016 < \lambda_Z < 0.016$.

[11] AAD 14Y determine the electroweak Z-dijet cross section in 8 TeV pp collisions. $Z \to ee$ and $Z \to \mu\mu$ decays are selected with the di-lepton $p_T > 20$ GeV and mass in the 81–101 GeV range. Minimum two jets are required with $p_T > 55$ and 45 GeV and no additional jets with $p_T > 25$ GeV in the rapidity interval between them. The normalized p_T balance between the Z and the two jets is required to be < 0.15. This leads to a selection of 900 events with dijet mass > 1 TeV. The number of signal and background events expected is 261 and 592 respectively. A Poisson likelihood method is used on an event by event basis to obtain the 95% CL limit $-0.15 < \lambda_Z < 0.13$ for a form factor value $\Lambda = \infty$.

[12] AAD 13AL study WW production in pp collisions and select 1325 WW candidates in decay modes with electrons or muons with an expected background of 369 ± 61 events. Assuming the LEP formulation and setting the form-factor Λ = infinity, a fit to the transverse momentum distribution of the leading charged lepton, leads to a 95% C.L. range of $-0.062 < \lambda_Z < 0.059$. Supersedes AAD 12AC.

[13] CHATRCHYAN 13BF determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high p_T. The leptons have $p_T > 20$ GeV/c and are isolated. 1134 candidate events are observed with an expected SM background of 247 ± 34. The p_T distribution of the leading lepton is fitted to obtain 95% C.L. limits of $-0.048 \leq \lambda_Z \leq 0.048$.

[14] AAD 12CD study WZ production in pp collisions and select 317 WZ candidates in three $\ell\nu$ decay modes with an expected background of 68.0 ± 10.0 events. The resulting 95% C.L. range is: $-0.046 < \lambda_Z < 0.047$. Supersedes AAD 12V.

[15] AALTONEN 12AC study WZ production in $p\overline{p}$ collisions and select 63 WZ candidates in three $\ell\nu$ decay modes with an expected background of 7.9 ± 1.0 events. Based on the cross section and shape of the Z transverse momentum spectrum, the following 95% C.L. range is reported: $-0.08 < \lambda_Z < 0.10$ for a form factor of $\Lambda = 2$ TeV.

[16] ABAZOV 11 study the $p\overline{p} \to 3\ell\nu$ process arising in WZ production. They observe 34 WZ candidates with an estimated background of 6 events. An analysis of the p_T spectrum of the Z boson leads to a 95% C.L. limit of $-0.077 < \lambda_Z < 0.093$, for a form factor $\Lambda = 2$ TeV.

[17] AALTONEN 10K study $p\overline{p} \to W^+W^-$ with $W \to e/\mu\nu$. The p_T of the leading (second) lepton is required to be > 20 (10) GeV. The final number of events selected is 654 of which 320 ± 47 are estimated to be background. The 95% C.L. interval is $-0.16 < \lambda_Z < 0.16$ for $\Lambda = 1.5$ TeV and $-0.14 < \lambda_Z < 0.15$ for $\Lambda = 2$ TeV.

[18] ABAZOV 07Z set limits on anomalous TGCs using the measured cross section and $p_T(Z)$ distribution in WZ production with both the W and the Z decaying leptonically into electrons and muons. Setting the other couplings to their standard model values, the 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.17 < \lambda_Z < 0.21$.

[19] ABAZOV 06H study $\overline{p}p \to WW$ production with a subsequent decay $WW \to e^+\nu_e e^-\overline{\nu}_e$, $WW \to e^\pm\nu_e\mu^\mp\nu_\mu$ or $WW \to \mu^+\nu_\mu\mu^-\overline{\nu}_\mu$. The 95% C.L. limit for a form factor scale $\Lambda = 2$ TeV is $-0.39 < \lambda_Z < 0.39$, fixing κ_Z=1. With the assumption that the $WW\gamma$ and WWZ couplings are equal the 95% C.L. one-dimensional limit ($\Lambda = 2$ TeV) is $-0.29 < \lambda < 0.30$.

[20] ABAZOV 05S study $\overline{p}p \to WZ$ production with a subsequent trilepton decay to $\ell\nu\ell'\overline{\ell}'$ (ℓ and $\ell' = e$ or μ). Three events (estimated background 0.71 ± 0.08 events) with WZ decay characteristics are observed from which they derive limits on the anomalous WWZ couplings. The 95% CL limit for a form factor scale $\Lambda = 1.5$ TeV is $-0.48 < \lambda_Z < 0.48$, fixing g_1^Z and κ_Z to their Standard Model values.

g_5^Z

W ANOMALOUS MAGNETIC MOMENT

The full magnetic moment is given by $\mu_W = e(1+\kappa+\lambda)/2m_W$. In the Standard Model, at tree level, $\kappa = 1$ and $\lambda = 0$. Some papers have defined $\Delta\kappa = 1-\kappa$ and assume that $\lambda = 0$. Note that the electric quadrupole moment is given by $-e(\kappa-\lambda)/m_W^2$. A description of the parameterization of these moments and additional references can be found in HAGIWARA 87

and BAUR 88. The parameter Λ appearing in the theoretical limits below is a regularization cutoff which roughly corresponds to the energy scale where the structure of the *W* boson becomes manifest.

		[4] SAMUEL	92	THEO	
		[5] SAMUEL	91	THEO	
		[6] GRIFOLS	88	THEO	
		[7] GROTCH	87	THEO	
		[8] VANDERBIJ	87	THEO	
		[9] GRAU	85	THEO	
		[10] SUZUKI	85	THEO	
		[11] HERZOG	84	THEO	

[1] ABREU 01I combine results from e^+e^- interactions at 189 GeV leading to W^+W^-, $We\nu_e$, and $\nu\overline{\nu}\gamma$ final states with results from ABREU 99L at 183 GeV to determine Δg^Z_1, $\Delta\kappa_\gamma$, and λ_γ. $\Delta\kappa_\gamma$ and λ_γ are simultaneously floated in the fit to determine μ_W.

[2] ABE 95G report $-1.3 < \kappa < 3.2$ for λ=0 and $-0.7 < \lambda < 0.7$ for κ=1 in $p\overline{p} \to e\nu_e\gamma$X and $\mu\nu_\mu\gamma$X at $\sqrt{s} = 1.8$ TeV.

[3] ALITTI 92C measure $\kappa = 1^{+2.6}_{-2.2}$ and $\lambda = 0^{+1.7}_{-1.8}$ in $p\overline{p} \to e\nu\gamma+$ X at $\sqrt{s} = 630$ GeV. At 95%CL they report $-3.5 < \kappa < 5.9$ and $-3.6 < \lambda < 3.5$.

[4] SAMUEL 92 use preliminary CDF and UA2 data and find $-2.4 < \kappa < 3.7$ at 96%CL and $-3.1 < \kappa < 4.2$ at 95%CL respectively. They use data for $W\gamma$ production and radiative *W* decay.

[5] SAMUEL 91 use preliminary CDF data for $p\overline{p} \to W\gamma$X to obtain $-11.3 \leq \Delta\kappa \leq 10.9$. Note that their $\kappa = 1-\Delta\kappa$.

[6] GRIFOLS 88 uses deviation from ρ parameter to set limit $\Delta\kappa \lesssim 65\ (M^2_W/\Lambda^2)$.

[7] GROTCH 87 finds the limit $-37 < \Delta\kappa < 73.5$ (90% CL) from the experimental limits on $e^+e^- \to \nu\overline{\nu}\gamma$ assuming three neutrino generations and $-19.5 < \Delta\kappa < 56$ for four generations. Note their $\Delta\kappa$ has the opposite sign as our definition.

[8] VANDERBIJ 87 uses existing limits to the photon structure to obtain $|\Delta\kappa| < 33\ (m_W/\Lambda)$. In addition VANDERBIJ 87 discusses problems with using the ρ parameter of the Standard Model to determine $\Delta\kappa$.

[9] GRAU 85 uses the muon anomaly to derive a coupled limit on the anomalous magnetic dipole and electric quadrupole (λ) moments $1.05 > \Delta\kappa\ \ln(\Lambda/m_W) + \lambda/2 > -2.77$. In the Standard Model $\lambda = 0$.

[10] SUZUKI 85 uses partial-wave unitarity at high energies to obtain $|\Delta\kappa| \lesssim 190\ (m_W/\Lambda)^2$. From the anomalous magnetic moment of the muon, SUZUKI 85 obtains $|\Delta\kappa| \lesssim 2.2/\ln(\Lambda/m_W)$. Finally SUZUKI 85 uses deviations from the ρ parameter and obtains a very qualitative, order-of-magnitude limit $|\Delta\kappa| \lesssim 150\ (m_W/\Lambda)^4$ if $|\Delta\kappa| \ll 1$.

[11] HERZOG 84 consider the contribution of *W*-boson to muon magnetic moment including anomalous coupling of $WW\gamma$. Obtain a limit $-1 < \Delta\kappa < 3$ for $\Lambda \gtrsim 1$ TeV.

c_{WWW}/Λ^2, c_W/Λ^2, c_B/Λ^2

These couplings are used in EFT-based approaches to anomalous couplings. They are linearly related to the couplings discussed above.

[1] AAD 21AC study the differential cross-section for the electroweak production of dijets in association with a *Z* boson, where the *Z* boson decays to electrons or muons. The number of events selected in the data is 10,870 (12,125) in the electron (muon) channel. Analyzing the distribution of the azimuthal separation of the two jets, the following 95% C.L. limits are derived in units of TeV^{-2}: $-2.7 < c_{WWW}/\Lambda^2 < 5.8$, $-1.6 < \tilde{c}_{WWW}/\Lambda^2 < 2.0$, $-0.19 < c_W/\Lambda^2 < 0.41$, $-0.11 < \tilde{c}_W/\Lambda^2 < 0.14$, $-6.31 < c_{HWB}/\Lambda^2 < 1.01$, $0.23 < \tilde{c}_{HWB}/\Lambda^2 < 2.35$.

[2] AAD 21W analyze W^+W^- production in association with at least one jet. Events with exactly one oppositely-charged electron-muon pair and at least one hadronic jet of transverse momentum larger than 30 GeV (120 GeV) are selected. In the data, 89,239 (5,825) events are found, with a total Standard-Model expectation of 91600 ± 2500 (5980 ± 150). Analyzing the electron-muon invariant mass distribution, the following limit at 95% C.L. is obtained: $-0.33 < c_W/\Lambda^2 < 0.33$ ($-0.60 < c_W/\Lambda^2 < 0.58$), for a fixed choice of $\Lambda = 1$ TeV.

[3] SIRUNYAN 21G measure $W\gamma$ production where the *W* decays into electrons or muons. In the data, 385,224 (395,818) events are selected in the electron (muon) channel, with a total Standard-Model expectation of 396913±54686 (396257±22837) events. Analysing the photon transverse momentum distribution, the following 95% C.L. limits are derived in units of TeV^{-2}: $-0.90 < c_{WWW}/\Lambda^2 < 0.91$, $-40 < c_B/\Lambda^2 < 41$, $-0.45 < c_{\overline{W}WW}/\Lambda^2 < 0.45$, $-20 < c_{\overline{W}}/\Lambda^2 < 20$.

[4] SIRUNYAN 20BA study electroweak production of a *W* boson in association with two jets, using *W* decays in the electron or muon channel. The isolated muons (electrons) are required to have a transverse momentum larger than 25 (30) GeV, while the transverse momentum of the two jets has to be larger than 50 and 30 GeV. A total of 2.382 (1.051) million events are selected in the muon (electron) channel, with a Standard Model expectation of 2.39±0.17 (1.054±0.058) million events. Analysing the transverse momentum distribution of the charged leptons from *W* decay, the following 95% C.L. limits are obtained in units of TeV^{-2}: $-2.3 < c_{WWW}/\Lambda^2 < 2.5$, $-8.8 < c_W/\Lambda^2 < 16$, $-45 < c_B/\Lambda^2 < 46$. Combining these results with those from the closely-related electroweak *Z*-jet-jet production SIRUNYAN 18BZ, the limits become: $-1.8 < c_{WWW}/\Lambda^2 < 2.0$, $-5.8 < c_W/\Lambda^2 < 10$, $-43 < c_B/\Lambda^2 < 45$.

[5] SIRUNYAN 20BF study W^+W^- production with the *W* bosons decaying to electrons or muons. The leading (subleading) lepton is required to have a transverse momentum larger than 25 (20) GeV. Events with a same-flavor di-lepton invariant mass within 15 GeV of the *Z* mass are rejected, as are event with a third lepton of transverse momentum larger than 10 GeV. In the same- (different-) flavor category a total of 9,604 (20,270) events are selected while the number of expected events is 9640 ± 490 (20280 ± 430). Analyzing the different-flavor di-lepton invariant mass distribution, the following 95% C.L. limits are obtained in units of TeV^{-2}: $-1.8 < c_{WWW}/\Lambda^2 < 1.8$, $-3.6 < c_W/\Lambda^2 < 2.8$, $-9.4 < c_B/\Lambda^2 < 8.5$.

[6] AABOUD 19BA study *WW* production in decay modes with an electron and a muon. The charged leptons are each required to have a transverse momentum larger than 27 GeV and rapidity less than 2.5. The electron-muon system is required to have a mass larger than 55 GeV and a transverse momentum larger than 30 GeV. The missing transverse energy must be larger than 20 GeV. Events containing a jet with transverse momentum exceeding 35 GeV and rapidity smaller than 4.5 are rejected. A total of 12,659 events are selected in the data, with an expected background of 4240 ± 477 events. Analysing the transverse momentum spectrum of the leading charged lepton, the following 95% C.L. limits are derived in units of TeV^{-2}: $-3.4 < c_{WWW}/\Lambda^2 < 3.3$, $-7.4 < c_W/\Lambda^2 < 4.1$, $-21 < c_B/\Lambda^2 < 18$, $-1.6 < c_{\overline{W}WW}/\Lambda^2 < 1.6$, $-76 < c_{\overline{W}}/\Lambda^2 < 76$.

[7] SIRUNYAN 19AD study inclusive *WZ* production, with *W* and *Z* decaying to electrons or muons. The leading (subleading) charged lepton candidate from the *Z* boson decay is required to have a transverse momentum larger than 25 GeV (10 GeV). The charged lepton candidate from the *W* boson decay is required to have a transverse momentum larger than 25 GeV. The invariant mass of the two leptons from *Z* decay is required to be within 15 GeV of the *Z* mass, while the invariant mass of the tri-lepton system is required to exceed 100 GeV. A total of 3,831 tri-lepton events are observed, with a fitted SM *WZ* signal of 3166 ± 62 events and a fitted background of 666 ± 45 events. The approximated *WZ* invariant mass distribution is analyzed to set 95% C.L. limits as follows: $-4.1 < c_W/\Lambda^2 < 1.1$, $-2.0 < c_{WWW}/\Lambda^2 < 2.1$, $-100 < c_B/\Lambda^2 < 160$, in units of TeV^{-2}.

[8] SIRUNYAN 19CL study *WW* and *WZ* production in lepton + jet events, with one *W* boson decaying leptonically (electron or muon), and another *W* or *Z* boson decaying hadronically, reconstructed as a single massive large-radius jet. In the electron channel 2,456 (2,235) events are selected in the *WW*(*WZ*) category, while in the muon channel 3,996 (3572) events are selected in the *WW*(*WZ*) category. Analysing the di-boson invariant mass distribution, the following 95% C.L. limits are obtained in units of TeV^{-2}: $-1.58 < c_{WWW}/\Lambda^2 < 1.59$, $-2.00 < c_W/\Lambda^2 < 2.65$, $-8.78 < c_B/\Lambda^2 < 8.54$.

[9] AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e\,2\mu$, and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading *Z* boson, the following the following 95% C.L. limits are derived in units of TeV^{-4}: $-5.9 < c_{\widetilde{B}\,W}/\Lambda^4 < 5.9$, $-3.0 < c_{WW}/\Lambda^4 < 3.0$, $-3.3 < c_{BW}/\Lambda^4 < 3.3$, $-2.7 < c_{BB}/\Lambda^4 < 2.8$.

[10] SIRUNYAN 18BZ study $pp \to Z$ *jet jet* events at 13 TeV where $Z \to e^+e^-/\mu^+\mu^-$. Isolated electrons and muons are selected with p_T of the leading/sub-leading lepton > 30/20 GeV and $|\eta| < 2.4$, with the di-lepton invariant mass within 15 GeV of the *Z* mass. The two highest p_T jets are selected with p_T of the leading/sub-leading jet > 50/30 GeV respectively and dijet invariant mass > 200 GeV. Templates in the transverse momentum of the *Z* are utilized to set limits on the triple gauge couplings in the EFT and the LEP parametrizations. The following 95% C.L. limits are obtained in units of TeV^{-2}: $-2.6 < c_{WWW}/\Lambda^2 < 2.6$ and $-8.4 < c_W/\Lambda^2 < 10.1$.

[11] AABOUD 17S analyze electroweak production of a *W* boson in association with two jets at high dijet invariant mass, with the *W* boson decaying to electron or muon plus neutrino. In the signal region of dijet mass larger than 1 TeV and leading-jet transverse momentum larger than 600 GeV, 30 events are observed in the data with 39 ± 4 events expected in the Standard Model, yielding the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-33 < c_W/\Lambda^2 < 30$, $-170 < c_B/\Lambda^2 < 160$, $-13 < c_{WWW}/\Lambda^2 < 9$, $-580 < c_{\widetilde{W}}/\Lambda^2 < 580$, $-11 < c_{\widetilde{W}WW}/\Lambda^2 < 11$, in units of TeV^{-2}.

[12] AABOUD 17U analyze production of *WW* or *WZ* boson pairs with one *W* boson decaying to electron or muon plus neutrino, and the other *W* or *Z* boson decaying hadronically. The hadronic decay system is reconstructed as either a resolved two-jet system or as a single large jet. Analysing the transverse momentum distribution of the hadronic system above 100 GeV yields the following limits at 95% CL for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-3.1 < c_{WWW}/\Lambda^2 < 3.1$, $-19 < c_B/\Lambda^2 < 20$, $-5.1 < c_W/\Lambda^2 < 5.8$, in units of TeV^{-2}.

[13] KHACHATRYAN 17O analyse *WZ* production where each boson decays into electrons or muons. Events are required to have a tri-lepton invariant mass larger than 100 GeV,

with one of the lepton pairs having an invariant mass within 20 GeV of the Z boson mass. The Z transverse momentum spectrum is analyzed to set 95% C.L. limits of: $-260 < c_B/\Lambda^2 < 210$, $-4.2 < c_W/\Lambda^2 < 8.0$, $-4.6 < c_{WWW}/\Lambda^2 < 4.2$, in units of TeV^{-2}.

[14] SIRUNYAN 17X study $pp \to WW/WZ \to \ell\nu q\overline{q}$ production at 8 TeV where ℓ is an electron or muon with $p_T > 30$ or 25 GeV respectively. Suitable cuts are put on the p_T of the dijet system and the missing E_T of the event yielding a total of 285 and 204 WV events observed in the electron and muon channels. The following 95% C.L. limits in units of TeV^{-2} are obtained: $-2.7 < c_{WWW}/\Lambda^2 < 2.7$, $-14 < c_B/\Lambda^2 < 17$, $-2.0 < c_W/\Lambda^2 < 5.7$.

[15] AAD 16AR study WW production in pp collisions and select 6636 WW candidates in decay modes with electrons or muons with an expected background of 1546 ± 157 events. Assuming an EFT formulation, a fit to the transverse momentum distribution of the leading charged lepton, leads to 95% C.L. ranges of: $-4.61 < c_{WWW}/\Lambda^2 < 4.60$, $-5.87 < c_W/\Lambda^2 < 10.54$ and $-20.9 < c_B/\Lambda^2 < 26.3$,in units of TeV^{-2}.

[16] AAD 16P study WZ production in pp collisions and select 2091 WZ candidates in 4 decay modes with electrons and muons, with an expected background of 1825 ± 7 events. Analyzing the WZ transverse momentum distribution, the resulting 95% C.L. limits are: $-3.9 < c_{WWW}/\Lambda^2 < 4.0$, $-4.3 < c_W/\Lambda^2 < 6.8$, and $-320 < c_B/\Lambda^2 < 210$, in units of TeV^{-2}.

[17] KHACHATRYAN 16BI determine the W^+W^- production cross section using unlike sign di-lepton (e or μ) events with high p_T. The leptons have $p_T > 20$ GeV/c and are isolated. Events are required to have no jets above p_T of 30 GeV/c. 4847 (2233) events are selected with different (same) flavor leptons, with an expected total background of 1179 ± 123 (643 ± 73) events. Analysing the di-lepton invariant mass spectrum, the following values are obtained: $c_{WWW}/\Lambda^2 = 0.1 \pm 3.2$, $c_W/\Lambda^2 = -3.6^{+5.0}_{-4.5}$ and $c_B/\Lambda^2 = -3.2^{+15.0}_{-14.5}$, in units of TeV^{-2}. The limits at 95% C.L. are: $-5.7 < c_{WWW}/\Lambda^2 < 5.9$, $-11.4 < c_W/\Lambda^2 < 5.4$ and $-29.2 < c_B/\Lambda^2 < 23.9$, in units of TeV^{-2}.

ANOMALOUS *W/Z* QUARTIC COUPLINGS

Revised November 2015 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\frac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$L_6^c = -\frac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^{\beta}\cdot\vec{W}_{\alpha}$$
$$L_6^n = -i\frac{e^2}{16\Lambda^2}\, a_n \epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha} F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\frac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$\widetilde{L}_6^n = -i\frac{e^2}{16\Lambda^2}\, \widetilde{a}_n \epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha} \widetilde{F}^{\mu\nu}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately ($\widetilde{L}_6^0$ conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP ($\widetilde{L}_6^n$ violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP-violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2, where $V = W$ or Z.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}]\times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is Λ, and $g = e/sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i}$, $i = 1, 2$, $f_{M,i}$, $i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5, which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

Anomalous W quartic couplings are measured by the experiments at LEP, the Tevatron, and the LHC. Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below). As discussed in the review on the "Anomalous W/Z quartic couplings (QGCS)," the measurements are typically done using different operator expansions which then do not allow the results to be compared and averaged. At least one common framework should be agreed upon for the use in the future publications by the experiments.

Some publications from LHC experiments derive limits for various assumed values of the form-factor cutoff Λ_{FF}. The values quoted below are for $\Lambda_{FF} \to \infty$.

[1] SIRUNYAN 21 study electroweak Z-pair production in association with two jets, with the Z bosons decaying to oppositely-charged electron or muon pairs. Leptons with high transverse momentum are selected, with the di-lepton invariant mass of the two Z boson candidates between 60 GeV and 120 GeV, and the four-lepton invariant mass larger than 180 GeV. A total of 365 events are selected in the data, while the number of expected events is 370 $\pm$ 48. Analyzing the four-lepton invariant mass distribution, the following 95% C.L. limits are derived: $-0.24 < f_{T,0}/\Lambda^4 < 0.22$, $-0.31 < f_{T,1}/\Lambda^4 < 0.31$, $-0.63 < f_{T,2}/\Lambda^4 < 0.59$, $-0.43 < f_{T,8}/\Lambda^4 < 0.43$, $-0.92 < f_{T,9}/\Lambda^4 < 0.92$, in units of TeV^{-4}.

[2] TUMASYAN 21A study electroweak $Z\gamma$ production in association with two jets, where the Z boson decays to electron or muon pairs and the pair of two jets has high invariant mass, superseeding SIRUNYAN 20AL. The number of observed (expected) electron events in the barrel and endcap regions are 375 (349 $\pm$ 9) and 174 (166 $\pm$ 6) events, respectively, while for muon events the respective numbers are 584 (612 $\pm$ 13) and 320 (303 $\pm$ 8). Analysing the $Z\gamma$ invariant mass distribution, the following 95% C.L. limits are derived: $-15.8 < f_{M,0}/\Lambda^4 < 16.0$, $-35.0 < f_{M,1}/\Lambda^4 < 34.7$, $-6.55 < f_{M,2}/\Lambda^4 < 6.49$, $-13.0 < f_{M,3}/\Lambda^4 < 13.0$, $-13.0 < f_{M,4}/\Lambda^4 < 12.7$, $-22.2 < f_{M,5}/\Lambda^4 < 21.3$, $-56.6 < f_{M,7}/\Lambda^4 < 55.9$, $-0.64 < f_{T,0}/\Lambda^4 < 0.57$, $-0.81 < f_{T,1}/\Lambda^4 < 0.90$, $-1.68 < f_{T,2}/\Lambda^4 < 1.54$, $-0.58 < f_{T,5}/\Lambda^4 < 0.64$, $-1.30 < f_{T,6}/\Lambda^4 < 1.33$, $-2.15 < f_{T,7}/\Lambda^4 < 2.43$, $-0.47 < f_{T,8}/\Lambda^4 < 0.47$, $-0.91 < f_{T,9}/\Lambda^4 < 0.91$, in units of TeV^{-4}.

[3] TUMASYAN 21B measure W or Z boson production in association with two photons, using the leptonic decays modes of W and Z with electrons or muons. The number of selected $W \to e(\mu)\nu$ events is 1987 (2384) and the number of selected $Z \to ee(\mu\mu)$ events is 110 (272) respectively. Analyzing the transverse momentum of the di-photon system, the following 95 % C.L. limits are derived in units of TeV^{-4}: In the W production channel, the observed limits are: $-39.9 < f_{M,2}/\Lambda^4 < 39.5$, $-63.8 < f_{M,3}/\Lambda^4 < 65.0$, $-1.30 < f_{T,0}/\Lambda^4 < 1.30$, $-1.70 < f_{T,1}/\Lambda^4 < 1.66$, $-3.64 < f_{T,2}/\Lambda^4 < 3.64$, $-0.52 < f_{T,5}/\Lambda^4 < 0.60$, $-0.60 < f_{T,6}/\Lambda^4 < 0.68$, $-1.16 < f_{T,7}/\Lambda^4 < 1.16$. In the Z production channel, the observed limits are: $-5.70 < f_{T,0}/\Lambda^4 < 5.46$, $-5.70 < f_{T,1}/\Lambda^4 < 5.46$, $-11.4 < f_{T,2}/\Lambda^4 < 10.9$, $-2.92 < f_{T,5}/\Lambda^4 < 2.92$, $-3.80 < f_{T,6}/\Lambda^4 < 3.88$, $-7.88 < f_{T,7}/\Lambda^4 < 7.72$, $-1.06 < f_{T,8}/\Lambda^4 < 1.10$, $-1.82 < f_{T,9}/\Lambda^4 < 1.82$, in units of TeV^{-4}.

[4] SIRUNAYN 20 study WZ and same-sign WW production in association with two jets, using the leptonic decays modes of the W and Z bosons with electrons or muons. Overall, 524 WW events and 229 WZ events are selected, with a Standard Model expectation of 535 $\pm$ 52 and 216 $\pm$ 21 events, respectively. Analyzing the transverse mass spectrum of the di-boson system and the di-jet invariant mass, the following 95% C.L. limits are derived, not using any unitarization procedure: $-0.25 < f_{T,0}/\Lambda^4 < 0.28$, $-0.12 < f_{T,1}/\Lambda^4 < 0.14$, $-0.35 < f_{T,2}/\Lambda^4 < 0.48$, $-2.7 < f_{M,0}/\Lambda^4 < 2.9$, $-4.1 < f_{M,1}/\Lambda^4 < 4.2$, $-5.4 < f_{M,6}/\Lambda^4 < 5.8$, $-5.7 < f_{M,7}/\Lambda^4 < 6.0$, $-5.7 < f_{S,0}/\Lambda^4 < 6.1$, $-16 < f_{S,1}/\Lambda^4 < 17$, in units of TeV^{-4}. The article also reports limits on these couplings by cutting the EFT expansion at the unitarity limit.

[5] SIRUNYAN 20AL study electroweak production of a Z boson and a photon in association with two jets in the electron and muon decay modes of the Z. A signal with a significance of 3.9 standard deviations is observed, compared to a Standard Model expectation of 5.2 standard deviations. Combining with KHACHATRYAN 17AA data at 8 TeV the final observed and expected signal significance is 4.7 and 5.5 standard deviations. Analyzing the Z-photon invariant mass distribution, the following 95% C.L. limits are derived: $-19.5 < f_{M,0}/\Lambda^4 < 20.3$, $-40.5 < f_{M,1}/\Lambda^4 < 39.5$, $-8.22 < f_{M,2}/\Lambda^4 < 8.10$, $-17.7 < f_{M,3}/\Lambda^4 < 17.9$, $-15.3 < f_{M,4}/\Lambda^4 < 15.8$, $-25.1 < f_{M,5}/\Lambda^4 < 24.5$, $-38.9 < f_{M,6}/\Lambda^4 < 40.6$, $-60.3 < f_{M,7}/\Lambda^4 < 62.5$, $-0.74 < f_{T,0}/\Lambda^4 < 0.69$, $-0.98 < f_{T,1}/\Lambda^4 < 0.96$, $-1.97 < f_{T,2}/\Lambda^4 < 1.86$, $-0.70 < f_{T,5}/\Lambda^4 < 0.75$, $-1.64 < f_{T,6}/\Lambda^4 < 1.68$, $-2.59 < f_{T,7}/\Lambda^4 < 2.82$, $-0.47 < f_{T,8}/\Lambda^4 < 0.47$, $-1.27 < f_{T,9}/\Lambda^4 < 1.27$, in units of TeV^{-4}.

[6] SIRUNYAN 20BD study electroweak $W\gamma$ production in association with two jets, where the W boson decays to electron or muon and the two jets have high invariant mass. The number of observed (expected) electron events with the photon in the barrel and endcap regions are 393 (397.1 $\pm$ 18.5) and 159 (145.2 $\pm$ 10.0) respectively, while for muon events the respective numbers are 565 (537.9 $\pm$ 21.4) and 201 (188.2 $\pm$ 10.5). Analyzing the $W\gamma$ invariant mass distribution, the following 95% C.L. limits are derived: $-8.1 < f_{M,0}/\Lambda^4 < 8.0$, $-12 < f_{M,1}/\Lambda^4 < 12$, $-2.8 < f_{M,2}/\Lambda^4 < 2.8$, $-4.4 < f_{M,3}/\Lambda^4 < 4.4$, $-5.0 < f_{M,4}/\Lambda^4 < 5.0$, $-8.3 < f_{M,5}/\Lambda^4 < 8.3$, $-16 < f_{M,6}/\Lambda^4 < 16$, $-21 < f_{M,7}/\Lambda^4 < 20$, $-0.6 < f_{T,0}/\Lambda^4 < 0.6$, $-0.4 < f_{T,1}/\Lambda^4 < 0.4$, $-1.0 < f_{T,2}/\Lambda^4 < 1.2$, $-0.5 < f_{T,5}/\Lambda^4 < 0.5$, $-0.4 < f_{T,6}/\Lambda^4 < 0.4$, $-0.9 < f_{T,7}/\Lambda^4 < 0.9$, in units of TeV^{-4}.

[7] SIRUNYAN 19BM search for the final state $W^+W^-W^\pm$ using W decays to electrons or muons. Two event samples are considered, events with three leptons, or events with two oppositely charged leptons accompanied by two jets. In a kinematic region selected to enhance the effect of anomalous couplings, no events are selected in the data, and 95% C.L. upper limits are obtained as follows: $-1.2 < f_{T,0}/\Lambda^4 < 1.2$, $-3.3 < f_{T,1}/\Lambda^4 < 3.3$, $-2.7 < f_{T,2}/\Lambda^4 < 2.6$, in units of TeV^{-4} and without application of a form factor.

[8] SIRUNYAN 19BP study WZ plus 2 jets production, using W and Z decay channels with electrons or muons. In the data, 75 events are selected, with a fitted SM signal of 15.1 $\pm$ 1.6 events and a fitted background of 62.4 $\pm$ 2.8 events. The transverse mass distribution of the WZ system is analyzed to set the following limits at 95% C.L., in units of TeV^{-4}: $-9.15 < f_{M,0}/\Lambda^4 < 9.15$, $-9.15 < f_{M,1}/\Lambda^4 < 9.45$, $-26.5 < f_{S,0}/\Lambda^4 < 27.5$, $-41.2 < f_{S,1}/\Lambda^4 < 42.8$, $-0.75 < f_{T,0}/\Lambda^4 < 0.81$, $-0.49 < f_{T,1}/\Lambda^4 < 0.55$, $-1.49 < f_{T,2}/\Lambda^4 < 1.85$.

[9] SIRUNYAN 19CQ search for anomalous electroweak production of vector boson pairs in association with two jets. Events are selected by requiring two jets with a large invariant mass and rapidity separation, one or two leptons (electrons or muons), and a W or Z boson decaying hadronically. In the WV (ZV) channel, 347 (47) events are selected in the data, with a total expected background of 352 $\pm$ 19 (50.3 $\pm$ 5.8) events. Analysing the mass distribution of the WV or ZV system, the following 95% C.L. limits are obtained: $-2.7 < f_{S,0}/\Lambda^4 < 2.7$, $-3.4 < f_{S,1}/\Lambda^4 < 3.4$, $-0.69 < f_{M,0}/\Lambda^4 < 0.70$, $-2.0 < f_{M,1}/\Lambda^4 < 2.1$, $-1.3 < f_{M,6}/\Lambda^4 < 1.3$, $-3.4 < f_{M,7}/\Lambda^4 < 3.4$, $-0.12 < f_{T,0}/\Lambda^4 < 0.11$, $-0.12 < f_{T,1}/\Lambda^4 < 0.13$, $-0.28 < f_{T,2}/\Lambda^4 < 0.28$, in units of TeV^{-4}.

[10] SIRUNYAN 18CC study pp collisions at $\sqrt{s}$ = 13 TeV leading to a pair of same-sign W pairs decaying leptonically (e or μ) associated with a pair of jets. Isolated leptons

with $p_T > 25$ (20) GeV for the leading (trailing) lepton, with $|\eta| < 2.5$ (2.4) for e (μ) and jets with $p_T > 30$ GeV, $|\eta| < 5.0$, $|\Delta\eta_{jj}| > 2.5$ and $m_{jj} > 500$ GeV is required. Further cuts are applied to minimize $Z \to e\,e$ events, non-prompt leptons and hadronically decaying taus. The number of selected events is 201, with an expected SM signal of 66.9 ± 2.4 and background of 138 ± 13 events. Analysing the dilepton invariant mass spectrum the following 95% C.L. limits are derived: $-7.7 < f_{S,0}/\Lambda^4 < 7.7$, $-21.6 < f_{S,1}/\Lambda^4 < 21.8$, $-6.0 < f_{M,0}/\Lambda^4 < 5.9$, $-8.7 < f_{M,1}/\Lambda^4 < 9.1$, $-11.9 < f_{M,6}/\Lambda^4 < 11.8$, $-13.3 < f_{M,7}/\Lambda^4 < 12.9$, $-0.62 < f_{T,0}/\Lambda^4 < 0.65$, $-0.28 < f_{T,1}/\Lambda^4 < 0.31$, $-0.89 < f_{T,2}/\Lambda^4 < 1.02$.

[11] AABOUD 17AA analyze $W^\pm W^\pm$ production in association with two jets and W decay modes with electrons or muons. In the kinematic region of VBS the effect of anomalous QGCs is enhanced by requiring the transverse mass of the WW system to be larger than 400 GeV. In the data, 8 events are selected with a total background expected from SM processes of 3.8 ± 0.6 events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the QGCs: $-0.14 < \alpha_4 < 0.15$ and $-0.22 < \alpha_5 < 0.22$. Supersedes AAD 14AM.

[12] AABOUD 17AG determine the $WW\gamma$ and $WZ\gamma$ cross sections in 8 TeV pp interactions by studying the final states $e\nu\mu\nu\gamma$ and $e\nu jj\gamma$ or $\mu\nu jj\gamma$. Upper limits on the production cross sections are derived in a fiducial region optimized for BSM physics. These are used to derive the following 95% C.L. upper limits for quartic couplings assuming the form scale factor, $\Lambda_{FF} = \infty$ (all in units of 10^3 TeV^{-4}): $-0.3 < f_{M,0}/\Lambda^4 < 0.3$, $-0.5 < f_{M,1}/\Lambda^4 < 0.5$, $-1.8 < f_{M,2}/\Lambda^4 < 1.8$, $-1.1 < f_{M,4}/\Lambda^4 < 1.1$, $-1.7 < f_{M,5}/\Lambda^4 < 1.7$, $-0.6 < f_{M,6}/\Lambda^4 < 0.6$, $-1.1 < f_{M,7}/\Lambda^4 < 1.1$, $-0.1 < f_{T,0}/\Lambda^4 < 0.1$, $-0.2 < f_{T,1}/\Lambda^4 < 0.2$, $-0.4 < f_{T,4}/\Lambda^4 < 0.4$, $-1.5 < f_{T,5}/\Lambda^4 < 1.6$, $-1.9 < f_{T,6}/\Lambda^4 < 1.9$, $-4.3 < f_{T,7}/\Lambda^4 < 4.3$.

[13] AABOUD 17D analyze electroweak diboson (WV, $V = W, Z$) production in association with a high-mass dijet system. In the data, 32 events are selected with an expected total background of 32 ± 12 events. Analysing the transverse mass distribution of the WV system, the following limits are set at 95% C.L.: $-0.024 < \alpha_4 < 0.030$ and $-0.028 < \alpha_5 < 0.033$.

[14] AABOUD 17J analyze the $Z\gamma$ production in association with a high-mass dijet system, with the Z boson decaying into a pair of electrons, muons, or neutrinos. In the charged lepton (neutrino) channel, events are selected with a dijet mass larger than 500 (600) GeV and a transverse photon energy larger than 250 (150) GeV, with 2 (4) events selected in the data and 0.30 ± 0.08 (1.6 ± 0.5) expected background events. The observed event yield is used to determine 95% CL limits as follows: $-4.1 \times 10^3 < f_{T,9}/\Lambda^4 < 4.2 \times 10^3$, $-1.9 \times 10^3 < f_{T,8}/\Lambda^4 < 2.1 \times 10^3$, $-1.9 \times 10^1 < f_{T,0}/\Lambda^4 < 1.6 \times 10^1$, $-1.6 \times 10^2 < f_{M,0}/\Lambda^4 < 1.8 \times 10^2$, $-3.5 \times 10^2 < f_{M,1}/\Lambda^4 < 3.4 \times 10^2$, $-8.9 \times 10^2 < f_{M,2}/\Lambda^4 < 8.9 \times 10^2$, $-1.7 \times 10^3 < f_{M,3}/\Lambda^4 < 1.7 \times 10^3$, in units of TeV^{-4} and without application of a form factor.

[15] AABOUD 17M analyze tri-boson $W^\pm W^\pm W^\mp$ production in decay channels with three charged leptons or two like-sign charged leptons with two jets, where the lepton can be an electron or muon. In the data, 24 tri-lepton events and 21 di-lepton plus jets events are selected, compared to a total event yield expected in the SM of 30.8 ± 3.0 and 21.9 ± 2.0, respectively. Analysing the tri-lepton transverse mass or the transverse momentum sum of the two leptons, two jets and the missing transverse energy, the following limits at 95% CL are derived for the form factor cut-off scale $\Lambda_{FF} \to \infty$: $-0.13 < f_{S,0}/\Lambda^4 < 0.18$, $-0.21 < f_{S,1}/\Lambda^4 < 0.27$, in units of 10^4 TeV^{-4}, which are converted into the following limits: $-0.49 < \alpha_4 < 0.75$ and $-0.48 < \alpha_5 < 0.62$.

[16] KHACHATRYAN 17AA analyse electroweak production of $Z\gamma$ in association with two hadronic jets, with the Z boson decaying to electron or muon pairs. Events with photon transverse momentum larger than 60 GeV and di-jet invariant mass larger than 400 GeV are selected. The $Z\gamma$ inavariant mass spectrum is analysed to set 95% C.L. limits as follows: $-71 < f_{M,0}/\Lambda^4 < 75$, $-190 < f_{M,1}/\Lambda^4 < 182$, $-32 < f_{M,2}/\Lambda^4 < 31$, $-58 < f_{M,3}/\Lambda^4 < 59$, $-3.8 < f_{T,0}/\Lambda^4 < 3.4$, $-4.4 < f_{T,1}/\Lambda^4 < 4.4$, $-9.9 < f_{T,2}/\Lambda^4 < 9.0$, $-1.8 < f_{T,8}/\Lambda^4 < 1.8$, $-4.0 < f_{T,9}/\Lambda^4 < 4.0$, in units of TeV^{-4} and without application of a form factor.

[17] KHACHATRYAN 17M analyse electroweak production of $W\gamma$ in association with two hadronic jets, with the W boson decaying to electrons or muons. Events with photon transverse momentum larger than 200 GeV and di-jet invariant mass larger than 200 GeV are selected. The W transverse momentum spectrum is analysed to set 95% C.L. limits as follows: $-77 < f_{M,0}/\Lambda^4 < 74$, $-125 < f_{M,1}/\Lambda^4 < 129$, $-26 < f_{M,2}/\Lambda^4 < 26$, $-43 < f_{M,3}/\Lambda^4 < 44$, $-40 < f_{M,4}/\Lambda^4 < 40$, $-65 < f_{M,5}/\Lambda^4 < 65$, $-129 < f_{M,6}/\Lambda^4 < 129$, $-164 < f_{M,7}/\Lambda^4 < 162$, $-5.4 < f_{T,0}/\Lambda^4 < 5.6$, $-3.7 < f_{T,1}/\Lambda^4 < 4.0$, $-11 < f_{T,2}/\Lambda^4 < 12$, $-3.8 < f_{T,5}/\Lambda^4 < 3.8$, $-2.8 < f_{T,6}/\Lambda^4 < 3.0$, $-7.3 < f_{T,7}/\Lambda^4 < 7.7$, in units of TeV^{-4} and without application of a form factor.

[18] SIRUNYAN 17AD study pp collisions at $\sqrt{s} = 13$ TeV to determine the cross section of $ZZjj$ with the Z decaying to $e\,e$ or $\mu\mu$. The ZZ mass distribution is used to set upper limits on the anomalous quartic couplings. The 95% upper limits for the relevant quartic couplings in units of TeV^{-4} are: $-0.46 < f_{T,0}/\Lambda^4 < 0.44$, $-0.61 < f_{T,1}/\Lambda^4 < 0.61$, $-1.2 < f_{T,2}/\Lambda^4 < 1.2$, $-0.84 < f_{T,8}/\Lambda^4 < 0.84$, $-1.8 < f_{T,9}/\Lambda^4 < 1.8$.

[19] SIRUNYAN 17AR study pp collisions at $\sqrt{s} = 8$ TeV to determine the cross section of $pp \to W\gamma\gamma$ and $pp \to Z\gamma\gamma$ where $W \to \ell\nu$ and $Z \to \ell^+\ell^-$, ℓ being an electron or a muon. The number of W events in the e and μ channels is 63 and 108 respectively, and the number of Z events in the e and μ channels is 117 and 141. To increase sensitivity, the transverse momentum of the leading photon is required to be larger than 70 GeV. The 95% C.L. upper limits in units of TeV^{-4} are $-701 < f_{M,2}/\Lambda^4 < 683$, $-1170 < f_{M,3}/\Lambda^4 < 1220$, $-33.5 < f_{T,0}/\Lambda^4 < 34.0$, $-44.3 < f_{T,1}/\Lambda^4 < 44.8$, $-93.8 < f_{T,2}/\Lambda^4 < 93.2$.

[20] AABOUD 16E study WW production in two-photon mediated pp collisions at 8 TeV where the W boson decays into an electron or muon, probing the $\gamma\gamma WW$ vertex for anomalous quartic gauge couplings. The lepton p_T is required to be larger than 30 GeV. Limits on anomalous couplings are determined from events with p_T larger than 120 GeV where the aQGC effect is enhanced and the SM background reduced; in the data corresponding to an integrated luminosity of 20.2fb^{-1}, 1 event is selected with an expected SM background of 0.37 ± 0.13 events. The 95% C.L. limits without a form-factor cutoff ($\Lambda_{\text{cutoff}} \to \infty$) are as follows: $-1.7 < a_0^W/\Lambda^2 < 1.7$ and $-6.4 < a_C^W/\Lambda^2 < 6.3$ in units of 10^{-6} GeV^{-2}. In terms of another set of variables: $-6.6 < f_{M,0}/\Lambda^4 < 6.6$ and $-24 < f_{M,1}/\Lambda^4 < 25$ in units of 10^{-11} GeV^{-4}.

[21] AAD 16Q study $Z\gamma\gamma$ production in pp collisions. In events with no additional jets, 29 (22) Z decays to electron (muon) pairs are selected, with an expected background of 3.3 ± 1.1 (6.5 ± 2.0) events, as well as 19 Z decays to netrino pairs with an expected background of 8.3 ± 4.4 events. Analysing the photon transverse momentum distribution for $m_{\gamma\gamma}$ above 200 GeV (300 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-1.6 \times 10^4 < f_{M,2}/\Lambda^4 < 1.6 \times 10^4$, $-2.9 \times 10^4 < f_{M,3}/\Lambda^4 < 2.7 \times 10^4$, $-0.86 \times 10^2 < f_{T,0}/\Lambda^4 < 1.03 \times 10^2$, $-0.69 \times 10^3 < f_{T,5}/\Lambda^4 < 0.68 \times 10^3$, $-0.74 \times 10^4 < f_{T,9}/\Lambda^4 < 0.74 \times 10^4$ in units of TeV^{-4} and without application of a form factor Λ_{FF}.

[22] KHACHATRYAN 16AX searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 13 events containing an $e^\pm\mu^\mp$ pair with $p_T(e, \mu) > 30$ GeV are selected in a total luminosity of 19.7 fb^{-1}, with an expected $\gamma\gamma \to WW$ signal of 5.3 ± 0.1 events and an expected background of 3.9 ± 0.5 events. When combining with the data collected at 7 TeV (CHATRCHYAN 13AA), and not assuming a form factor, the following 1-parameter limits at 95% C.L. are obtained from the $p_T(e, \mu)$ spectrum: $|a_0^W/\Lambda^2| < 1.1 \times 10^{-6}$ GeV^{-2} ($a_C^W = 0$), and $|a_C^W/\Lambda^2| < 4.1 \times 10^{-6}$ GeV^{-2} ($a_0^W = 0$). In terms of another set of variables: $|f_{M,0}/\Lambda^4| < 4.2 \times 10^{-12}$ GeV^{-4}, $|f_{M,1}/\Lambda^4| < 16 \times 10^{-12}$ GeV^{-4}, $|f_{M,2}/\Lambda^4| < 2.1 \times 10^{-12}$ GeV^{-4}, $|f_{M,3}/\Lambda^4| < 7.8 \times 10^{-12}$ GeV^{-4}.

[23] AAD 15N study $WW\gamma\gamma$ events in 8 TeV pp interactions, where the W decays into an electron or a muon. The events are characterized by an isolated lepton, a missing transverse energy due to the decay neutrino, and two isolated photons, with the p_T of the lepton and the photons being > 20 GeV. The number of candidate events observed in the electron channel for N(jet) ≥ 0 and N(jet) $= 0$ is 47 and 15, the corresponding numbers for the muon channel being 110 and 53. The backgrounds expected are 30.2 ± 7.4, 8.7 ± 3.0, 52.1 ± 12.2, and 24.4 ± 8.3 respectively. The 95% C.L. limits on the values of the parameters $f_{T,0}/\Lambda^4$, $f_{M,2}/\Lambda^4$ and $f_{M,3}/\Lambda^4$ are -0.9–0.9×10^2, -0.8–0.8×10^4, and -1.5–1.4×10^4 respectively, without application of a form factor Λ_{FF}.

[24] KHACHATRYAN 15D study vector-boson-scattering tagged by two jets, requiring two same-sign charged leptons arising from $W^\pm W^\pm$ production and decay. The two jets must have a transverse momentum larger than 30 GeV, while the leptons, electrons or muons, must have a transverse momentum > 20 GeV. The dijet mass is required to be > 500 GeV, the dilepton mass > 50 GeV, with additional requirement of differing from the Z mass by > 15 GeV. In the two categories W^+W^+ and W^-W^-, 10 and 2 data events are observed in a data sample corresponding to an integrated luminosity of 19.4 fb^{-1}, with an expected background of 3.1 ± 0.6 and 2.6 ± 0.5 events. Analysing the distribution of the dilepton invariant mass, the following limits at 95% C.L. are obtained, in units of TeV^{-4}: $-38 < F_{S,0}/\Lambda^4 < 40$, $-118 < F_{S,1}/\Lambda^4 < 120$, $-33 < F_{M,0}/\Lambda^4 < 32$, $-44 < F_{M,1}/\Lambda^4 < 47$, $-65 < F_{M,6}/\Lambda^4 < 63$, $-70 < F_{M,7}/\Lambda^4 < 66$, $-4.2 < F_{T,0}/\Lambda^4 < 4.6$, $-1.9 < F_{T,1}/\Lambda^4 < 2.2$, $-5.2 < F_{T,2}/\Lambda^4 < 6.4$.

[25] AAD 14AM analyze electroweak production of WW jet jet same-charge diboson plus two jets production, with the W bosons decaying to electron or muon, to study the quartic $WWWW$ coupling. In a kinematic region enhancing the electroweak production over the strong production, 34 events are observed in the data while 29.8 ± 2.4 events are expected with a backgound of 15.9 ± 1.9 events. Assuming the other QGC coupling to have the SM value of zero, the observed event yield is used to determine 95% CL limits on the quartic gauge couplings: $-0.14 < \alpha_4 < 0.16$ and $-0.23 < \alpha_5 < 0.24$.

[26] CHATRCHYAN 14Q study $WV\gamma$ production in 8 TeV pp collisions, in the single lepton final state, with $W \to \ell\nu$, $Z \to$ dijet or $W \to \ell\nu$, $W \to$ dijet, the dijet mass resolution precluding differentiation between the W and Z. p_T and pseudo-rapidity cuts are put on the lepton, the photon and the two jets to minimize backgrounds. The dijet mass is required to be between 70–100 GeV and $|\Delta\eta_{jj}| < 1.4$. The selected number of muon (electron) events are 183 (139), with SM expectation being 194.2 ± 11.5 (147.9 ± 10.7) including signal and background. The photon E_T distribution is used to set limits on the anomalous quartic couplings. The following 95% CL limits are deduced (all in units of TeV^{-2} or TeV^{-4}): $-21 < a_0^W/\Lambda^2 < 20$, $-34 < a_c^W/\Lambda^2 < 32$, $-12 < \kappa_0^W/\Lambda^2 < 10$ and $-18 < \kappa_c^W/\Lambda^2 < 17$; and $-25 < f_{T,0}/\Lambda^4 < 24$ TeV^{-4}.

[27] ABAZOV 13D searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 946 events containing an e^+e^- pair with missing energy are selected in a total luminosity of 9.7 fb^{-1}, with an expectation of 983 ± 108 events from Standard-Model processes. The following 1-parameter limits at 95% CL are otained: $|a_0^W/\Lambda^2| < 4.3 \times 10^{-4}$ GeV^{-2} ($a_c^W = 0$), $|a_c^W/\Lambda^2| < 1.5 \times 10^{-3}$ GeV^{-2} ($a_0^W = 0$).

[28] CHATRCHYAN 13AA searches for anomalous $WW\gamma\gamma$ quartic gauge couplings in the two-photon-mediated process $pp \to ppWW$, assuming the $WW\gamma$ triple gauge boson couplings to be at their Standard Model values. 2 events containing an $e^\pm\mu^\mp$ pair with $p_T(e, \mu) > 30$ GeV are selected in a total luminosity of 5.05 fb^{-1}, with an expected $ppWW$ signal of 2.2 ± 0.4 events and an expected background of 0.84 ± 0.15 events. The following 1-parameter limits at 95% CL are otained from the $p_T(e, \mu)$ spectrum: $|a_0^W/\Lambda^2| < 4.0 \times 10^{-6}$ GeV^{-2} ($a_c^W = 0$), $|a_c^W/\Lambda^2| < 1.5 \times 10^{-5}$ GeV^{-2} ($a_0^W = 0$).

[29] ABBIENDI 04B select 187 $e^+e^- \to W^+W^-\gamma$ events in the C.M. energy range 180–209 GeV, where $E_\gamma > 2.5$ GeV, the photon has a polar angle $|\cos\theta_\gamma| < 0.975$ and is well isolated from the nearest jet and charged lepton, and the effective masses of both fermion-antifermion systems agree with the W mass within $3\,\Gamma_W$. The measured differential cross section as a function of the photon energy and photon polar angle is used to extract the 95% CL limits: -0.020 GeV$^{-2} < a_0/\Lambda^2 < 0.020$ GeV^{-2}, -0.053 GeV$^{-2} < a_c/\Lambda^2 < 0.037$ GeV^{-2} and -0.16 GeV$^{-2} < a_n/\Lambda^2 < 0.15$ GeV^{-2}.

[30] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples

are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV^{-2}, $-0.029 < a_c^Z/\Lambda^2 < 0.029$ GeV^{-2}, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV^{-2}, $-0.052 < a_c^W/\Lambda^2 < 0.037$ GeV^{-2}.

31 In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \rightarrow \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T_\gamma}/E_{beam} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV^{-2}, $-0.041 < a_c^Z/\Lambda^2 < 0.044$ GeV^{-2}, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV^{-2}, $-0.099 < a_c^W/\Lambda^2 < 0.093$ GeV^{-2}.

32 ABDALLAH 03I select 122 $e^+e^- \rightarrow W^+W^-\gamma$ events in the C.M. energy range 189–209 GeV, where $E_\gamma > 5$ GeV, the photon has a polar angle $|\cos\theta_\gamma| < 0.95$ and is well isolated from the nearest charged fermion. A fit to the photon energy spectra yields $a_c/\Lambda^2 = 0.000^{+0.019}_{-0.040}$ GeV^{-2}, $a_0/\Lambda^2 = -0.004^{+0.018}_{-0.010}$ GeV^{-2}, $\tilde{a}_0/\Lambda^2 = -0.007^{+0.019}_{-0.008}$ GeV^{-2}, $a_n/\Lambda^2 = -0.09^{+0.16}_{-0.05}$ GeV^{-2}, and $\tilde{a}_n/\Lambda^2 = +0.05^{+0.07}_{-0.15}$ GeV^{-2}, keeping the other parameters fixed to their Standard Model values (0). The 95% CL limits are: -0.063 GeV^{-2} $< a_c/\Lambda^2 < +0.032$ GeV^{-2}, -0.020 GeV^{-2} $< a_0/\Lambda^2 < +0.020$ GeV^{-2}, -0.020 GeV^{-2} $< \tilde{a}_0/\Lambda^2 < +0.020$ GeV^{-2}, -0.18 GeV^{-2} $< a_n/\Lambda^2 < +0.14$ GeV^{-2}, -0.16 GeV^{-2} $< \tilde{a}_n/\Lambda^2 < +0.17$ GeV^{-2}.

33 ACHARD 02F select 86 $e^+e^- \rightarrow W^+W^-\gamma$ events at 192–207 GeV, where $E_\gamma > 5$ GeV and the photon is well isolated. They also select 43 acoplanar $e^+e^- \rightarrow \nu\overline{\nu}\gamma\gamma$ events in this energy range, where the photon energies are >5 GeV and >1 GeV and the photon polar angles are between 14° and 166°. All these 43 events are in the recoil mass region corresponding to the Z (75–110 GeV). Using the shape and normalization of the photon spectra in the $W^+W^-\gamma$ events, and combining with the 42 event sample from 189 GeV data (ACCIARRI 00T), they obtain: $a_0/\Lambda^2 = 0.000 \pm 0.010$ GeV^{-2}, $a_c/\Lambda^2 = -0.013 \pm 0.023$ GeV^{-2}, and $a_n/\Lambda^2 = -0.002 \pm 0.076$ GeV^{-2}. Further combining the analyses of $W^+W^-\gamma$ events with the low recoil mass region of $\nu\overline{\nu}\gamma\gamma$ events (including samples collected at 183 + 189 GeV), they obtain the following one-parameter 95% CL limits: -0.015 GeV^{-2} $< a_0/\Lambda^2 < 0.015$ GeV^{-2}, -0.048 GeV^{-2} $< a_c/\Lambda^2 < 0.026$ GeV^{-2}, and -0.14 GeV^{-2} $< a_n/\Lambda^2 < 0.13$ GeV^{-2}.

Z Boson

Z MASS

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). The fit is performed using the Z mass and width, the Z hadronic pole cross section, the ratios of hadronic to leptonic partial widths, and the Z pole forward-backward lepton asymmetries. This set is believed to be most free of correlations.

The Z-boson mass listed here corresponds to the mass parameter in a Breit-Wigner distribution with mass dependent width. The value is 34 MeV greater than the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator. Also the LEP experiments have generally assumed a fixed value of the $\gamma - Z$ interferences term based on the standard model. Keeping this term as free parameter leads to a somewhat larger error on the fitted Z mass. See ACCIARRI 00Q and ABBIENDI 04G for a detailed investigation of both these issues.

91.272 ±0.032 ±0.033		[7] ACHARD	04C	L3	$E_{\rm cm}^{ee}$= 183–209 GeV
91.1875±0.0039	3.97M	[8] ACCIARRI	00Q	L3	$E_{\rm cm}^{ee}$= LEP1 + 130–189 GeV
91.151 ±0.008		[9] MIYABAYASHI	95	TOPZ	$E_{\rm cm}^{ee}$= 57.8 GeV
91.74 ±0.28 ±0.93	156	[10] ALITTI	92B	UA2	$E_{\rm cm}^{p\overline{p}}$= 630 GeV
90.9 ±0.3 ±0.2	188	[11] ABE	89C	CDF	$E_{\rm cm}^{p\overline{p}}$= 1.8 TeV
91.14 ±0.12	480	[12] ABRAMS	89B	MRK2	$E_{\rm cm}^{ee}$= 89–93 GeV
93.1 ±1.0 ±3.0	24	[13] ALBAJAR	89	UA1	$E_{\rm cm}^{p\overline{p}}$= 546,630 GeV

[1] ABBIENDI 01A error includes approximately 2.3 MeV due to statistics and 1.8 MeV due to LEP energy uncertainty.
[2] The error includes 1.6 MeV due to LEP energy uncertainty.
[3] The error includes 1.8 MeV due to LEP energy uncertainty.
[4] BARATE 00C error includes approximately 2.4 MeV due to statistics, 0.2 MeV due to experimental systematics, and 1.7 MeV due to LEP energy uncertainty.
[5] ANDREEV 18A obtain this result in a combined electroweak and QCD analysis using all deep-inelastic e^+p and e^-p neutral current and charged current scattering cross sections published by the H1 Collaboration, including data with longitudinally polarized lepton beams.
[6] ABBIENDI 04G obtain this result using the S–matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 34 MeV shift with respect to the Breit–Wigner fits.
[7] ACHARD 04C select $e^+e^- \to Z\gamma$ events with hard initial–state radiation. Z decays to $q\overline{q}$ and muon pairs are considered. The fit results obtained in the two samples are found consistent to each other and combined considering the uncertainty due to ISR modelling as fully correlated.
[8] ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 34.1 MeV shift with respect to the Breit-Wigner fits. The error contains a contribution of ±2.3 MeV due to the uncertainty on the γZ interference.
[9] MIYABAYASHI 95 combine their low energy total hadronic cross-section measurement with the ACTON 93D data and perform a fit using an S-matrix formalism. As expected, this result is below the mass values obtained with the standard Breit-Wigner parametrization.
[10] Enters fit through W/Z mass ratio given in the W Particle Listings. The ALITTI 92B systematic error (±0.93) has two contributions: one (±0.92) cancels in m_W/m_Z and one (±0.12) is noncancelling. These were added in quadrature.
[11] First error of ABE 89 is combination of statistical and systematic contributions; second is mass scale uncertainty.
[12] ABRAMS 89B uncertainty includes 35 MeV due to the absolute energy measurement.
[13] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.

Z WIDTH

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06).

2.7 ±2.0 ±1.0	25	[10] ANSARI	87	UA2	$E_{\rm cm}^{p\overline{p}}$= 546,630 GeV

[1] ABBIENDI 01A error includes approximately 3.6 MeV due to statistics, 1 MeV due to event selection systematics, and 1.3 MeV due to LEP energy uncertainty.
[2] The error includes 1.2 MeV due to LEP energy uncertainty.
[3] The error includes 1.3 MeV due to LEP energy uncertainty.
[4] BARATE 00C error includes approximately 3.8 MeV due to statistics, 0.9 MeV due to experimental systematics, and 1.3 MeV due to LEP energy uncertainty.
[5] ABBIENDI 04G obtain this result using the S–matrix formalism for a combined fit to their cross section and asymmetry data at the Z peak and their data at 130–209 GeV. The authors have corrected the measurement for the 1 MeV shift with respect to the Breit–Wigner fits.
[6] ACCIARRI 00Q interpret the s-dependence of the cross sections and lepton forward-backward asymmetries in the framework of the S-matrix formalism. They fit to their cross section and asymmetry data at high energies, using the results of S-matrix fits to Z-peak data (ACCIARRI 00C) as constraints. The 130–189 GeV data constrains the γ/Z interference term. The authors have corrected the measurement for the 0.9 MeV shift with respect to the Breit-Wigner fits.
[7] ABREU 96R obtain this value from a study of the interference between initial and final state radiation in the process $e^+e^- \to Z \to \mu^+\mu^-$.
[8] ABRAMS 89B uncertainty includes 50 MeV due to the miniSAM background subtraction error.
[9] ALBAJAR 89 result is from a total sample of 33 $Z \to e^+e^-$ events.
[10] Quoted values of ANSARI 87 are from direct fit. Ratio of Z and W production gives either $\Gamma(Z) < (1.09 \pm 0.07) \times \Gamma(W)$, CL = 90% or $\Gamma(Z) = (0.82^{+0.19}_{-0.14} \pm 0.06) \times \Gamma(W)$. Assuming Standard-Model value $\Gamma(W) = 2.65$ GeV then gives $\Gamma(Z) < 2.89 \pm 0.19$ or $= 2.17^{+0.50}_{-0.37} \pm 0.16$.

[a] This parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06 (Physics Reports (Physics Letters C) **427** 257 (2006)).

[b] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[c] Here ℓ indicates e or μ.

[d] The value is for the sum of the charge states or particle/antiparticle states indicated.

[e] This value is updated using the product of (i) the $Z \to b\overline{b}$ fraction from this listing and (ii) the b-hadron fraction in an unbiased sample of weakly decaying b-hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFLAV, http://www.slac.stanford.edu/xorg/hflav/osc/PDG_2009/#FRACZ).

[f] See the Particle Listings below for the γ energy range used in this measurement.

[g] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

Z PARTIAL WIDTHS

$\Gamma(e^+e^-)$ Γ_1

For the LEP experiments, this parameter is not directly used in the overall fit but is derived using the fit results; see the note "The Z boson" and ref. LEP-SLC 06.

$\Gamma(\ell^+\ell^-)$ Γ_4

ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

In our fit $\Gamma(\ell^+\ell^-)$ is defined as the partial Z width for the decay into a pair of massless charged leptons. This parameter is not directly used in the 5-parameter fit assuming lepton universality but is derived using the fit results. See the note "The Z boson" and ref. LEP-SLC 06.

4.31±0.34±0.17	172	AAD	14N	ATLS	E_{cm}^{pp} = 7, 8 TeV
$4.6\ ^{+1.0}_{-0.9}$ ±0.2	28	[5] CHATRCHYAN	12BN	CMS	E_{cm}^{pp} = 7 TeV

[1] AAD 21AQ analyze differential cross-sections in four-lepton events. Based on the measured cross section in the $Z \to 4\ell$ channel, a branching fraction of $B(Z \to 4\ell) = (4.41 \pm 0.13 \pm 0.23 \pm 0.09 \pm 0.12) \times 10^{-6}$ is obtained, where the uncertainties are statistical, systematic, theory and luminosity, respectively.
[2] AABOUD 19N reports $(4.70 \pm 0.32 \pm 0.21 \pm 0.14) \times 10^{-6}$, where the uncertainties are statistical, systematic, and luminosity. We have combined the latter two in quadrature.
[3] SIRUNYAN 18BT report the $Z \to 4\ell$ branching fraction $= (4.83^{+0.23+0.32}_{-0.22-0.29} \pm 0.08 \pm 0.12) \times 10^{-6}$, where the uncertainties are statistical, systematic, due to theory, and luminosity. The last three have been added in quadrature to obtain the total systematic error.
[4] KHACHATRYAN 16CC reports $(4.9^{+0.8+0.3+0.2+0.1}_{-0.7-0.2-0.1-0.1}) \times 10^{-6}$ value, where the uncertainties are statistical, systematic, theory, and due to luminosity. We have combined uncertainties in quadrature.
[5] CHATRCHYAN 12BN reports $(4.2^{+0.9}_{-0.8} \pm 0.2) \times 10^{-6}$ value. Their result (both central value and uncertainties) is scaled up by 10% to account for the different phase-space definition used here (see RAINBOLT 19).

0.1623±0.0085±0.0209	[6] ABREU	95D	DLPH	E_{cm}^{ee}= 88–94 GeV

[1] ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events using a double tag method. The single c–tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere). A multitag approach is used, defining 4 regions of the output value of the neural network and R_c is extracted from a simultaneous fit to the count rates of the 4 different tags. The quoted systematic error includes an uncertainty of ±0.0006 due to the uncertainty on R_b.

[2] ABREU 00 obtain this result properly combining the measurement from the D^{*+} production rate (R_c= 0.1610 ± 0.0104 ± 0.0077 ± 0.0043 (BR)) with that from the overall charm counting (R_c= 0.1692 ± 0.0047 ± 0.0063 ± 0.0074 (BR)) in $c\overline{c}$ events. The systematic error includes an uncertainty of ±0.0054 due to the uncertainty on the charmed hadron branching fractions.

[3] BARATE 00B use exclusive decay modes to independently determine the quantities $R_c \times f(c \to X)$, X=D^0, D^+, D_s^+, and Λ_c. Estimating $R_c \times f(c \to \Xi_c/\Omega_c)$= 0.0034, they simply sum over all the charm decays to obtain R_c= 0.1738 ± 0.0047 ± 0.0088 ± 0.0075(BR). This is combined with all previous ALEPH measurements (BARATE 98T and BUSKULIC 94G, R_c= 0.1681 ± 0.0054 ± 0.0062) to obtain the quoted value.

[4] ACKERSTAFF 98E use an inclusive/exclusive double tag. In one jet $D^{*\pm}$ mesons are exclusively reconstructed in several decay channels and in the opposite jet a slow pion (opposite charge inclusive $D^{*\pm}$) tag is used. The b content of this sample is measured by the simultaneous detection of a lepton in one jet and an inclusively reconstructed $D^{*\pm}$ meson in the opposite jet. The systematic error includes an uncertainty of ±0.006 due to the external branching ratios.

[5] ALEXANDER 96R obtain this value via direct charm counting, summing the partial contributions from D^0, D^+, D_s^+, and Λ_c^+, and assuming that strange-charmed baryons account for the 15% of the Λ_c^+ production. An uncertainty of ±0.005 due to the uncertainties in the charm hadron branching ratios is included in the overall systematics.

[6] ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ±0.0124 due to models and branching ratios.

$R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$ Γ_{12}/Γ_8

OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

The Standard Model predicts R_b=0.21581 for m_t=174.3 GeV and M_H=150 GeV.

[1] ABE 05F use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events using a double tag method. The single b–tag is obtained with a neural network trained to perform flavor discrimination using as input several signatures (corrected secondary vertex mass, vertex decay length, multiplicity and total momentum of the hemisphere; the key tag is obtained requiring the secondary vertex corrected mass to be above the D–meson mass). ABE 05F obtain R_b =0.21604 ± 0.00098 ± 0.00074 where the systematic error includes an uncertainty of ±0.00012 due to the uncertainty on R_c. The value reported here is obtained properly combining with ABE 98D. The quoted systematic error includes an uncertainty of ±0.00012 due to the uncertainty on R_c.

[2] ACCIARRI 00 obtain this result using a double-tagging technique, with a high p_T lepton tag and an impact parameter tag in opposite hemispheres.

[3] ABBIENDI 99B tag $Z \to b\overline{b}$ decays using leptons and/or separated decay vertices. The b-tagging efficiency is measured directly from the data using a double-tagging technique.

[4] ABREU 99B obtain this result combining in a multivariate analysis several tagging methods (impact parameter and secondary vertex reconstruction, complemented by event shape variables). For R_c different from its Standard Model value of 0.172, R_b varies as $-0.024\times(R_c-0.172)$.

[5] BARATE 97F combine the lifetime-mass hemisphere tag (BARATE 97E) with event shape information and lepton tag to identify $Z \to b\overline{b}$ candidates. They further use c- and uds-selection tags to identify the background. For R_c different from its Standard Model value of 0.172, R_b varies as $-0.019\times(R_c - 0.172)$.

[6] ABREU 95D perform a maximum likelihood fit to the combined p and p_T distributions of single and dilepton samples. The second error includes an uncertainty of ±0.0023 due to models and branching ratios.

[7] BUSKULIC 94G perform a simultaneous fit to the p and p_T spectra of both single and dilepton events.

[8] JACOBSEN 91 tagged $b\overline{b}$ events by requiring coincidence of ≥ 3 tracks with significant impact parameters using vertex detector. Systematic error includes lifetime and decay uncertainties (±0.014).

$<2.6\times10^{-6}$	95	[3] AAD	15I	ATLS	E_{cm}^{pp} = 8 TeV

[1] SIRUNYAN 19AJ study $Z\to J/\psi\gamma$ with $J/\psi\to\mu^+\mu^-$. Candidate events are selected by requiring a pair of oppositely charged muons and a well isolated photon. The leading (subleading) muon is require to have a transverse momentum larger than 20 GeV (4 GeV), while the photon must have a transverse energy larger than 33 GeV. Requiring the invariant mass of the $\mu\mu$ ($\mu\mu\gamma$) system in the range 3.0 to 3.2 (81 to 101) GeV, selects 183 data events which is consistent with the expected background. The 95% C.L. limit on the Z branching fraction is obtained assuming the J/ψ to be unpolarized.

[2] AABOUD 18BL study $Z\to J/\psi\gamma$ in 13 TeV pp interactions. Two triggers were used: isolated photon of $p_T>35(25)$ GeV and a muon with $p_T>18(24)$ GeV. The J/ψ is detected via its dimuon decay and it is required that the azimuthal angle between the photon and the J/ψ in the plane transverse to the beam direction is $>\pi/2$. The number of observed/expected background events is $92/89\pm6$ in the dimuon mass range 2.9–3.3 GeV leading to the quoted 95% C.L. limit.

[3] AAD 15I use events with the highest p_T muon in the pair required to have $p_T>20$ GeV, the dimuon mass required to be within 0.2 GeV of the $J/\psi(1S)$ mass and it's transverse momentum required to be >36 GeV. The photon is also required to have it's $p_T>36$ GeV.

VALUE	DOCUMENT ID		TECN	COMMENT
$0.67\pm0.18\pm0.05$	[1] SIRUNYAN	18DZ	CMS	pp at 13 TeV

[1] SIRUNYAN 18DZ observe the decay $Z\to\Psi\ell^+\ell^-$ in pp collisions at $\sqrt{s}=13$ TeV, where Ψ includes J/ψ as well as $\psi(2S)\to J/\psi X$, and $\ell^+\ell^-$ represents an electron or muon pair while the J/ψ is detected via its $\mu^+\mu^-$ decay channel. To reduce systematic errors they determine the ratio of the branching fraction of this decay to that of $Z\to\mu^+\mu^-\mu^+\mu^-$ within phase-space cuts imposed on lepton transverse momentum and pseudo rapidity, dilepton invariant mass, and J/ψ transverse momentum. The number of selected $\Psi\mu^+\mu^-$ (Ψe^+e^-) candidate events is 29 (18). Analyzing the $\mu^+\mu^-$ and $\mu^+\mu^-\ell^+\ell^-$ invariant mass distributions, a yield of 13.0 ± 3.9 (11.2 ± 3.4) events for the $\Psi\mu^+\mu^-$ (Ψe^+e^-) mode is obtained. The ratio of the branching fractions is determined as $0.67\pm0.18\pm0.05$ within the selected phase-space cuts. Assuming extrapolation to full phase space cancels in the ratio, and using their measured value of $B(Z\to\mu^+\mu^-\mu^+\mu^-)=(1.20\pm0.08)\times10^{-6}$, they estimate $B(Z\to J/\psi\ell^+\ell^-)=8\times10^{-7}$.

seen	[1] ABDALLAH	05C	DLPH	E_{cm}^{ee} = 88–94 GeV

[1] ABDALLAH 05C searched for the charmed strange baryon Ξ_c^0 in the decay channel $\Xi_c^0 \to \Xi^-\pi^+$ ($\Xi^- \to \Lambda\pi^-$). The production rate is measured to be $f_{\Xi_c^0} \times B(\Xi_c^0 \to \Xi^-\pi^+) = (4.7 \pm 1.4 \pm 1.1)\times10^{-4}$ per hadronic Z decay.

$\Gamma(\Xi_b X)/\Gamma(\text{hadrons})$ Γ_{55}/Γ_8

Here Ξ_b is used as a notation for the strange b-baryon states Ξ_b^- and Ξ_b^0.

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
seen	[1] ABDALLAH	05C	DLPH	E_{cm}^{ee} = 88–94 GeV
seen	[2] BUSKULIC	96T	ALEP	E_{cm}^{ee} = 88–94 GeV
seen	[3] ABREU	95V	DLPH	E_{cm}^{ee} = 88–94 GeV

[1] ABDALLAH 05C searched for the beauty strange baryon Ξ_b in the inclusive semileptonic decay channel $\Xi_b \to \Xi^-\ell^-\overline{\nu}_\ell X$. Evidence for the Ξ_b production is seen from the observation of $\Xi^\mp$ production accompanied by a lepton of the same sign. From the excess of "right-sign" pairs $\Xi^\mp\ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp\ell^\pm$ the production rate is measured to be $B(b \to \Xi_b) \times B(\Xi_b \to \Xi^-\ell^- X) = (3.0 \pm 1.0 \pm 0.3)\times10^{-4}$ per lepton species, averaged over electrons and muons.

[2] BUSKULIC 96T investigate Ξ-lepton correlations and find a significant excess of "right–sign" pairs $\Xi^\mp\ell^\mp$ compared to "wrong–sign" pairs $\Xi^\mp\ell^\pm$. This excess is interpreted as evidence for Ξ_b semileptonic decay. The measured product branching ratio is $B(b \to \Xi_b) \times B(\Xi_b \to X_c X\ell^-\overline{\nu}_\ell) \times B(X_c \to \Xi^- X') = (5.4 \pm 1.1 \pm 0.8)\times10^{-4}$ per lepton species, averaged over electrons and muons, with X_c a charmed baryon.

[3] ABREU 95V observe an excess of "right-sign" pairs $\Xi^\mp\ell^\mp$ compared to "wrong-sign" pairs $\Xi^\mp\ell^\pm$ in jets: this excess is interpreted as evidence for the beauty strange baryon Ξ_b production, with $\Xi_b \to \Xi^-\ell^-\overline{\nu}_\ell X$. They find that the probability for this signal to come from non b-baryon decays is less than 5×10^{-4} and that Λ_b decays can account for less than 10% of these events. The Ξ_b production rate is then measured to be $B(b \to \Xi_b) \times B(\Xi_b \to \Xi^-\ell^- X) = (5.9 \pm 2.1 \pm 1.0)\times10^{-4}$ per lepton species, averaged over electrons and muons.

$\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons})$ Γ_{56}/Γ_8

"OUR EVALUATION" is obtained using our current values for $f(b \to b\text{-baryon})$ and $R_b = \Gamma(b\overline{b})/\Gamma(\text{hadrons})$. We calculate $\Gamma(b\text{-baryon } X)/\Gamma(\text{hadrons}) = R_b \times f(b \to b\text{-baryon})$. The decay fraction $f(b \to b\text{-baryon})$ was provided by the Heavy Flavor Averaging Group (https://hflav.web.cern.ch/).

2.57±0.15 OUR AVERAGE				
2.59±0.03±0.16	[1] BEDDALL	09		ALEPH archive, E_{cm}^{ee}= 91.2 GeV
2.40±0.06±0.43	ACKERSTAFF	98A	OPAL	E_{cm}^{ee}= 91.2 GeV

[1] BEDDALL 09 analyse 3.2 million hadronic Z decays as archived by ALEPH collaboration and report a value of 2.59 ± 0.03 ± 0.15 ± 0.04. The first error is statistical, the second systematic, and the third arises from extrapolation to full phase space. We combine the systematic errors in quadrature.

Z HADRONIC POLE CROSS SECTION

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). This quantity is defined as

$$\sigma_h^0 = \frac{12\pi}{M_Z^2} \frac{\Gamma(e^+e^-)\,\Gamma(\text{hadrons})}{\Gamma_Z^2}$$

It is one of the parameters used in the Z lineshape fit.

[1] ABBIENDI 01A error includes approximately 0.031 due to statistics, 0.033 due to event selection systematics, 0.029 due to uncertainty in luminosity measurement, and 0.011 due to LEP energy uncertainty.

[2] BARATE 00C error includes approximately 0.030 due to statistics, 0.026 due to experimental systematics, and 0.025 due to uncertainty in luminosity measurement.

Z VECTOR COUPLINGS

These quantities are the effective vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e, A_μ, and A_τ. By convention the sign of g_A^e is fixed to be negative (and opposite to that of g^{ν_e} obtained using ν_e scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e, A_μ, and A_τ measurements. See the note "The Z boson" and ref. LEP-SLC 06 for details. Where $p\overline{p}$ and ep data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

$-0.0414\ \pm0.0020$		[4] ABE	95J	SLD	$E_{\rm cm}^{ee}=$ 91.31 GeV

[1] ACOSTA 05M determine the forward–backward asymmetry of e^+e^- pairs produced via $q\overline{q}\to Z/\gamma^*\to e^+e^-$ in 15 M(e^+e^-) effective mass bins ranging from 40 GeV to 600 GeV. These results are used to obtain the vector and axial–vector couplings of the Z to e^+e^-, assuming the quark couplings are as predicted by the standard model. Higher order radiative corrections have not been taken into account.
[2] ABBIENDI 01O use their measurement of the τ polarization in addition to the lineshape and forward-backward lepton asymmetries.
[3] ACCIARRI 00C use their measurement of the τ polarization in addition to forward-backward lepton asymmetries.
[4] ABE 95J obtain this result combining polarized Bhabha results with the A_{LR} measurement of ABE 94C. The Bhabha results alone give $-0.0507\pm0.0096\pm0.0020$.

Z AXIAL-VECTOR COUPLINGS

These quantities are the effective axial-vector couplings of the Z to charged leptons and quarks. Their magnitude is derived from a measurement of the Z lineshape and the forward-backward lepton asymmetries as a function of energy around the Z mass. The relative sign among the vector to axial-vector couplings is obtained from a measurement of the Z asymmetry parameters, A_e, A_μ, and A_τ. By convention the sign of g_A^e is fixed to be negative (and opposite to that of g^{ν_e} obtained using ν_e scattering measurements). For the light quarks, the sign of the couplings is assigned consistently with this assumption. The LEP/SLD-based fit values quoted below correspond to global nine- or five-parameter fits to lineshape, lepton forward-backward asymmetry, and A_e, A_μ, and A_τ measurements. See

the note "The Z boson" and ref. LEP-SLC 06 for details. Where $p\overline{p}$ and ep data is quoted, OUR FIT value corresponds to a weighted average of this with the LEP/SLD fit result.

VALUE	DOCUMENT ID		TECN	COMMENT
0.502±0.017	[1] VILAIN	94	CHM2	From $\nu_\mu e$ scattering

[1] VILAIN 94 derive this value from their measurement of the couplings $g_A^{e\nu_\mu} = -0.503 \pm 0.017$ and $g_V^{e\nu_\mu} = -0.035 \pm 0.017$ obtained from $\nu_\mu e$ scattering. We have re-evaluated this value using the current PDG values for g_A^e and g_V^e.

Z ASYMMETRY PARAMETERS

For each fermion-antifermion pair coupling to the Z these quantities are defined as

$$A_f = \frac{2g_V^f g_A^f}{(g_V^f)^2 + (g_A^f)^2}$$

where g_V^f and g_A^f are the effective vector and axial-vector couplings. For their relation to the various lepton asymmetries see the note "The Z boson" and ref. LEP-SLC 06.

A_e

Using polarized beams, this quantity can also be measured as $(\sigma_L - \sigma_R)/(\sigma_L + \sigma_R)$, where σ_L and σ_R are the e^+e^- production cross sections for Z bosons produced with left-handed and right-handed electrons respectively.

[1] ABBIENDI 01O fit for A_e and A_τ from measurements of the τ polarization at varying τ production angles. The correlation between A_e and A_τ is less than 0.03.

[2] ABE 01B use the left-right production and left-right forward-backward decay asymmetries in leptonic Z decays to obtain a value of 0.1544 ± 0.0060. This is combined with left-right production asymmetry measurement using hadronic Z decays (ABE 00B) to obtain the quoted value.

[3] HEISTER 01 obtain this result fitting the τ polarization as a function of the polar production angle of the τ.

[4] ABREU 00E obtain this result fitting the τ polarization as a function of the polar τ production angle. This measurement is a combination of different analyses (exclusive τ decay modes, inclusive hadronic 1-prong reconstruction, and a neural network analysis).

[5] Derived from the measurement of forward-backward τ polarization asymmetry.

[6] ABE 97 obtain this result from a measurement of the observed left-right charge asymmetry, $A_Q^{obs} = 0.225 \pm 0.056 \pm 0.019$, in hadronic Z decays. If they combine this value of A_Q^{obs} with their earlier measurement of A_{LR}^{obs} they determine A_e to be $0.1574 \pm 0.0197 \pm 0.0067$ independent of the beam polarization.

[7] ABE 95J obtain this result from polarized Bhabha scattering.

A_μ

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $\mu^+\mu^-$ production at SLC using a polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e.

0.153±0.012	1.7M	[2] AAD	15BT	ATLS	E_{cm}^{pp} = 7 TeV

[1] ABE 01B obtain this direct measurement using the left-right production and left-right forward-backward polar angle asymmetries in $\mu^+\mu^-$ decays of the Z boson obtained with a polarized electron beam.

[2] AAD 15BT study $pp \to Z \to \ell^+\ell^-$ events where ℓ is an electron or a muon in the dilepton mass region 70–1000 GeV. The background in the Z peak region is estimated to be < 1% for the muon channel. The muon asymmetry parameter is derived from the measured forward-backward asymmetry assuming the value of the quark asymmetry parameter from the SM. For this reason it is not used in the average.

A_τ

The LEP Collaborations derive this quantity from the measurement of the τ polarization in $Z \to \tau^+\tau^-$. The SLD Collaboration directly extracts this quantity from its measured left-right forward-backward asymmetry in $Z \to \tau^+\tau^-$ produced using a polarized e^- beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e.

[1] ABBIENDI 01O fit for A_e and A_τ from measurements of the τ polarization at varying τ production angles. The correlation between A_e and A_τ is less than 0.03.

[2] ABE 01B obtain this direct measurement using the left-right production and left-right forward-backward polar angle asymmetries in $\tau^+\tau^-$ decays of the Z boson obtained with a polarized electron beam.

[3] HEISTER 01 obtain this result fitting the τ polarization as a function of the polar production angle of the τ.

[4] ABREU 00E obtain this result fitting the τ polarization as a function of the polar τ production angle. This measurement is a combination of different analyses (exclusive τ decay modes, inclusive hadronic 1-prong reconstruction, and a neural network analysis).

A_s

The SLD Collaboration directly extracts this quantity by a simultaneous fit to four measured s-quark polar angle distributions corresponding to two states of e^- polarization (positive and negative) and to the K^+K^- and $K^\pm K_S^0$ strange particle tagging modes in the hadronic final states.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.895±0.066±0.062	2870	[1] ABE	00D	SLD	E_{cm}^{ee}= 91.2 GeV

[1] ABE 00D tag $Z \to s\overline{s}$ events by an absence of B or D hadrons and the presence in each hemisphere of a high momentum $K^\pm$ or K_S^0.

A_c

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $c\overline{c}$ production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e. OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

VALUE	DOCUMENT ID		TECN	COMMENT
0.670 ±0.027 OUR FIT				
0.6712±0.0224±0.0157	[1] ABE	05	SLD	E_{cm}^{ee}= 91.24 GeV
• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.583 ±0.055 ±0.055	[2] ABE	02G	SLD	E_{cm}^{ee}= 91.24 GeV
0.688 ±0.041	[3] ABE	01C	SLD	E_{cm}^{ee}= 91.25 GeV

[1] ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $c\overline{c}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying c–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (9970 events) $A_c = 0.6747 \pm 0.0290 \pm 0.0233$. Taking into account all correlations with earlier results reported in ABE 02G and ABE 01C, they obtain the quoted overall SLD result.

[2] ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c.

[3] ABE 01C tag $Z \to c\overline{c}$ events using two techniques: exclusive reconstruction of D^{*+}, D^+ and D^0 mesons and the soft pion tag for $D^{*+} \to D^0\pi^+$. The large background from D mesons produced in $b\overline{b}$ events is separated efficiently from the signal using precision vertex information. When combining the A_c values from these two samples, care is taken to avoid double counting of events common to the two samples, and common systematic errors are properly taken into account.

A_b

This quantity is directly extracted from a measurement of the left-right forward-backward asymmetry in $b\overline{b}$ production at SLC using polarized electron beam. This double asymmetry eliminates the dependence on the Z-e-e coupling parameter A_e. OUR FIT is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
0.907 ±0.020 ±0.024	48028	[2] ABE	03F	SLD	E_{cm}^{ee}= 91.24 GeV
0.919 ±0.030 ±0.024		[3] ABE	02G	SLD	E_{cm}^{ee}= 91.24 GeV
0.855 ±0.088 ±0.102	7473	[4] ABE	99L	SLD	E_{cm}^{ee}= 91.27 GeV

[1] ABE 05 use hadronic Z decays collected during 1996–98 to obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of reconstructed secondary decay vertices. The charge of the underlying b–quark is obtained with an algorithm that takes into account the net charge of the vertex as well as the charge of tracks emanating from the vertex and identified as kaons. This yields (25917 events) $A_b = 0.9173 \pm 0.0184 \pm 0.0173$. Taking into account all correlations with earlier results reported in ABE 03F, ABE 02G and ABE 99L, they obtain the quoted overall SLD result.

[2] ABE 03F obtain an enriched sample of $b\overline{b}$ events tagging on the invariant mass of a 3-dimensional topologically reconstructed secondary decay. The charge of the underlying b quark is obtained using a self-calibrating track-charge method. For the 1996–1998 data sample they measure $A_b = 0.906 \pm 0.022 \pm 0.023$. The value quoted here is obtained combining the above with the result of ABE 98I (1993–1995 data sample).

[3] ABE 02G tag b and c quarks through their semileptonic decays into electrons and muons. A maximum likelihood fit is performed to extract simultaneously A_b and A_c.

[4] ABE 99L obtain an enriched sample of $b\overline{b}$ events tagging with an inclusive vertex mass cut. For distinguishing b and $\overline{b}$ quarks they use the charge of identified $K^\pm$.

TRANSVERSE SPIN CORRELATIONS IN $Z \to \tau^+\tau^-$

The correlations between the transverse spin components of $\tau^+\tau^-$ produced in Z decays may be expressed in terms of the vector and axial-vector couplings:

$$C_{TT} = \frac{|g_A^\tau|^2 - |g_V^\tau|^2}{|g_A^\tau|^2 + |g_V^\tau|^2}$$

$$C_{TN} = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2 + |g_V^\tau|^2}\sin(\Phi_{g_V^\tau} - \Phi_{g_A^\tau})$$

C_{TT} refers to the transverse-transverse (within the collision plane) spin correlation and C_{TN} refers to the transverse-normal (to the collision plane) spin correlation.

The longitudinal τ polarization P_τ ($= -A_\tau$) is given by:

$$P_\tau = -2\frac{|g_A^\tau||g_V^\tau|}{|g_A^\tau|^2+|g_V^\tau|^2}\cos(\Phi_{g_V^\tau}-\Phi_{g_A^\tau})$$

Here Φ is the phase and the phase difference $\Phi_{g_V^\tau}-\Phi_{g_A^\tau}$ can be obtained using both the measurements of C_{TN} and P_τ.

C_{TT}

FORWARD-BACKWARD $e^+e^- \to f\overline{f}$ CHARGE ASYMMETRIES

These asymmetries are experimentally determined by tagging the respective lepton or quark flavor in e^+e^- interactions. Details of heavy flavor (c- or b-quark) tagging at LEP are described in the note on "The Z boson" and ref. LEP-SLC 06. The Standard Model predictions for LEP data have been (re)computed using the ZFITTER package (version 6.36) with input parameters M_Z=91.187 GeV, M_{top}=174.3 GeV, M_{Higgs}=150 GeV, α_S=0.119, $\alpha^{(5)}(M_Z)$= 1/128.877 and the Fermi constant $G_F = 1.16637\times10^{-5}$ GeV^{-2} (see the note on "The Z boson" for references). For non-LEP data the Standard Model predictions are as given by the authors of the respective publications.

$A_{FB}^{(0,e)}$ CHARGE ASYMMETRY IN $e^+e^- \to e^+e^-$

OUR FIT is obtained using the fit procedure and correlations as determined by the LEP Electroweak Working Group (see the note "The Z boson" and ref. LEP-SLC 06). For the Z peak, we report the pole asymmetry defined by $(3/4)A_e^2$ as determined by the nine-parameter fit to cross-section and lepton forward-backward asymmetry data.

[1] ABDALLAH 04F tag b– and c–quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of $c\overline{c}$ and $b\overline{b}$ events are obtained using lifetime information.

[2] ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B^0-$\overline{B}^0$ mixing.

[3] HEISTER 02H measure simultaneously b and c quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

[4] ABREU 99Y tag $Z \to b\overline{b}$ and $Z \to c\overline{c}$ events by an exclusive reconstruction of several D meson decay modes (D^{*+}, D^0, and D^+ with their charge-conjugate states).

[5] BARATE 98O tag $Z \to c\overline{c}$ events requiring the presence of high-momentum reconstructed D^{*+}, D^+, or D^0 mesons.

[6] ALEXANDER 97C identify the b and c events using a D/D^* tag.

[7] ADRIANI 92D use both electron and muon semileptonic decays.

$A_{FB}^{(0,b)}$ CHARGE ASYMMETRY IN $e^+e^- \to b\overline{b}$

OUR FIT, which is obtained by a simultaneous fit to several c- and b-quark measurements as explained in the note "The Z boson" and ref. LEP-SLC 06, refers to the **Z pole** asymmetry. The experimental values, on the other hand, correspond to the measurements carried out at the respective energies.

[1] ABDALLAH 05 obtain an enriched samples of $b\overline{b}$ events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.

[2] ABDALLAH 04F tag b– and c–quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of $c\overline{c}$ and $b\overline{b}$ events are obtained using lifetime information.

[3] ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the b and c quark forward-backward asymmetries as well as the average B^0-$\overline{B}^0$ mixing.

[4] ABBIENDI 02I tag $Z^0 \to b\overline{b}$ decays using a combination of secondary vertex and lepton tags. The sign of the b-quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.

[5] HEISTER 02H measure simultaneously b and c quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

[6] HEISTER 01D tag $Z \to b\overline{b}$ events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The b-quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of A_{FB}^c and R_b is given as $+0.103\ (A_{FB}^c - 0.0651) - 0.440\ (R_b - 0.21585)$.

[7] ABREU 99Y tag $Z \to b\overline{b}$ and $Z \to c\overline{c}$ events by an exclusive reconstruction of several D meson decay modes (D^{*+}, D^0, and D^+ with their charge-conjugate states).

[8] ACCIARRI 99D tag $Z \to b\overline{b}$ events using high p and p_T leptons. The analysis determines simultaneously a mixing parameter $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$ which is used to correct the observed asymmetry.

[9] ACCIARRI 98U tag $Z \to b\overline{b}$ events using lifetime and measure the jet charge using the hemisphere charge.

[10] ALEXANDER 97C identify the b and c events using a D/D^* tag.

CHARGE ASYMMETRY IN $e^+e^- \to q\overline{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on B^0-$\overline{B}^0$ mixing and on other electroweak parameters.

ANOMALOUS $ZZ\gamma$, $Z\gamma\gamma$, AND ZZV COUPLINGS

Revised September 2013 by M.W. Grünewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell $Z\gamma$ production, deviations from the Standard Model for the $Z\gamma\gamma^*$ and $Z\gamma Z^*$ couplings may be described in terms of eight parameters, h_i^V $(i = 1, 4;\ V = \gamma, Z)$ [1]. The parameters h_i^γ describe the $Z\gamma\gamma^*$ couplings and the parameters h_i^Z the $Z\gamma Z^*$ couplings. In this formalism h_1^V and h_2^V lead to CP-violating and h_3^V and h_4^V to CP-conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation, $h_i^V(s) = h_{i\circ}^V/(1 + s/\Lambda^2)^n$, where Λ is the energy scale for the manifestation of a new phenomenon and n is a sufficiently large power. By convention one uses $n = 3$ for $h_{1,3}^V$ and $n = 4$ for $h_{2,4}^V$. Usually limits on h_i^V's are put assuming some value of Λ, sometimes ∞.

In on-shell ZZ production, deviations from the Standard Model for the $ZZ\gamma^*$ and ZZZ^* couplings may be described by means of four anomalous couplings f_i^V $(i = 4, 5; V = \gamma, Z)$ [2]. As above, the parameters f_i^γ describe the $ZZ\gamma^*$ couplings and the parameters f_i^Z the ZZZ^* couplings. The anomalous couplings f_5^V lead to violation of C and P symmetries while f_4^V introduces CP violation. Also here, formfactors depending on a scale Λ are used.

All these couplings h_i^V and f_i^V are zero at tree level in the Standard Model; they are measured in e^+e^-, $p\overline{p}$ and pp collisions at LEP, Tevatron and LHC.

h_i^V

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.12 < h_1^Z < +0.11, \quad -0.07 < h_2^Z < +0.07,$$
$$-0.19 < h_3^Z < +0.06, \quad -0.04 < h_4^Z < +0.13,$$
$$-0.05 < h_1^\gamma < +0.05, \quad -0.04 < h_2^\gamma < +0.02,$$
$$-0.05 < h_3^\gamma < +0.00, \quad +0.01 < h_4^\gamma < +0.05.$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

[1] AAD 16Q study $Z\gamma$ production in pp collisions. In events with no additional jets, 10268 (12738) Z decays to electron (muon) pairs are selected, with an expected background of 1291 ± 340 (1537 ± 408) events, as well as 1039 Z decays to neutrino pairs with an expected background of 450 ± 96 events. Analyzing the photon transverse momentum distribution above 250 GeV (400 GeV) for lepton (neutrino) events, yields the 95% C.L. limits: $-7.8\times10^{-4} < h_3^Z < 8.6\times10^{-4}$, $-3.0\times10^{-6} < h_4^Z < 2.9\times10^{-6}$, $-9.5\times10^{-4} < h_3^\gamma < 9.9\times10^{-4}$, $-3.2\times10^{-6} < h_4^\gamma < 3.2\times10^{-6}$.

[2] KHACHATRYAN 16AE determine the $Z\gamma \to \nu\overline{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and $\not{E}_T > 140$ GeV. 630 candidate events are observed with an expected SM background of 269 ± 26. The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $-1.5\times10^{-3} < h_3^Z < 1.6\times10^{-3}$, $-3.9\times10^{-6} < h_4^Z < 4.5\times10^{-6}$, $-1.1\times10^{-3} < h_3^\gamma < 0.9\times10^{-3}$, $-3.8\times10^{-6} < h_4^\gamma < 4.3\times10^{-6}$.

[3] KHACHATRYAN 15AC study $Z\gamma$ events in 8 TeV pp interactions, where the Z decays into 2 same-flavor, opposite sign leptons (e or μ) and a photon with $p_T > 15$ GeV. The p_T of a lepton is required to be > 20 GeV/c, their effective mass > 50 GeV, and the photon should have a separation $\Delta R > 0.7$ with each lepton. The observed p_T distribution of the photons is used to extract the 95% C.L. limits: $-3.8\times10^{-3} < h_3^Z < 3.7\times10^{-3}$, $-3.1\times10^{-5} < h_4^Z < 3.0\times10^{-5}$, $-4.6\times10^{-3} < h_3^\gamma < 4.6\times10^{-3}$, $-3.6\times10^{-5} < h_4^\gamma < 3.5\times10^{-5}$.

[4] CHATRCHYAN 14AB measure $Z\gamma$ production cross section for $p_T^\gamma > 15$ GeV and $R(\ell\gamma) > 0.7$, which is the separation between the γ and the final state charged lepton (e or μ) in the azimuthal angle-pseudorapidity ($\phi - \eta$) plane. The di-lepton mass is required to be > 50 GeV. After background subtraction the number of $ee\gamma$ and $\mu\mu\gamma$ events is determined to be 3160 ± 120 and 5030 ± 233 respectively, compatible with expectations from the SM. This leads to a 95% CL limits of $-1\times10^{-2} < h_3^\gamma < 1\times10^{-2}$, $-9\times10^{-5} < h_4^\gamma < 9\times10^{-5}$, $-9\times10^{-3} < h_3^Z < 9\times10^{-3}$, $-8\times10^{-5} < h_4^Z < 8\times10^{-5}$, assuming h_1^V and h_2^V have SM values, $V = \gamma$ or Z.

[5] AAD 13AN study $Z\gamma$ production in pp collisions. In events with no additional jet, 1417 (2031) Z decays to electron (muon) pairs are selected, with an expected background of 156 ± 54 (244 ± 64) events, as well as 662 Z decays to neutrino pairs with an expected background of 302±42 events. Analysing the photon p_T spectrum above 100 GeV yields the 95% C.L. limts: $-0.013 < h_3^Z < 0.014$, $-8.7\times10^{-5} < h_4^Z < 8.7\times10^{-5}$, $-0.015 < h_3^\gamma < 0.016$, $-9.4\times10^{-5} < h_4^\gamma < 9.2\times10^{-5}$. Supersedes AAD 12BX.

[6] CHATRCHYAN 13BI determine the $Z\gamma \to \nu\overline{\nu}\gamma$ cross section by selecting events with a photon of $E_T > 145$ GeV and a $\not{E}_T > 130$ GeV. 73 candidate events are observed with an expected SM background of 30.2±6.5. The E_T spectrum of the photon is used to set 95% C.L. limits as follows: $|h_3^Z| < 2.7\times10^{-3}$, $|h_4^Z| < 1.3\times10^{-5}$, $|h_3^\gamma| < 2.9\times10^{-3}$, $|h_4^\gamma| < 1.5\times10^{-5}$.

[7] ABAZOV 12S study $Z\gamma$ production in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV using 6.2 fb^{-1} of data where the Z decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of 255 ± 16 (285 ± 24) events. Based on the photon p_T spectrum, and including also earlier data and the $Z \to \nu\overline{\nu}$ decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported: $|h_{03}^Z| < 0.026$, $|h_{04}^Z| < 0.0013$, $|h_{03}^\gamma| < 0.027$, $|h_{04}^\gamma| < 0.0014$ for a form factor scale of $\Lambda = 1.5$ TeV.

[8] AALTONEN 11S study $Z\gamma$ events in $p\overline{p}$ interactions at $\sqrt{s} = 1.96$ TeV with integrated luminosity 5.1 fb^{-1} for $Z \to e^+e^-/\mu^+\mu^-$ and 4.9 fb^{-1} for $Z \to \nu\overline{\nu}$. For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one > 20 GeV and the other > 10 GeV. The isolated photon must have $E_T > 50$ GeV. They observe 91 events with 87.2 ± 7.8 events expected from standard model processes. For the $\nu\overline{\nu}$ case they require solitary photons with $E_T > 25$ GeV and missing $E_T > 25$ GeV and observe 85 events with standard model expectation of 85.9 ± 5.6 events. Taking the form factor $\Lambda = 1.5$ TeV they derive 95% C.L. limits as $|h_3^{\gamma,Z}| < 0.022$ and $|h_4^{\gamma,Z}| < 0.0009$.

[9] CHATRCHYAN 11M study $Z\gamma$ production in pp collisions at $\sqrt{s} = 7$ TeV using 36 pb^{-1} pp data, where the Z decays to e^+e^- or $\mu^+\mu^-$. The total cross sections are measured for photon transverse energy $E_T^\gamma > 10$ GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle $\Delta R(\ell,\gamma) > 0.7$ with the dilepton invariant mass requirement of $M_{\ell\ell} > 50$ GeV. The number of $e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ candidates is 81 and 90 with estimated backgrounds of 20.5±2.5 and 27.3±3.2

events respectively. The 95% CL limits for $ZZ\gamma$ couplings are $-0.05 < h_3^Z < 0.06$ and $-0.0005 < h_4^Z < 0.0005$, and for $Z\gamma\gamma$ couplings are $-0.07 < h_3^\gamma < 0.07$ and $-0.0005 < h_4^\gamma < 0.0006$.

[10] ABAZOV 09L study $Z\gamma$, $Z \to \nu\overline{\nu}$ production in $p\overline{p}$ collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy E_T larger than 90 GeV, with an expected background of 17 events. Based on the photon E_T spectrum and including also Z decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported: $|h_{30}^\gamma| < 0.033$, $|h_{40}^\gamma| < 0.0017$, $|h_{30}^Z| < 0.033$, $|h_{40}^Z| < 0.0017$.

[11] ABAZOV 07M use 968 $p\overline{p} \to e^+e^-/\mu^+\mu^-\gamma X$ candidates, at 1.96 TeV center of mass energy, to tag $p\overline{p} \to Z\gamma$ events by requiring $E_T(\gamma) > 7$ GeV, lepton-gamma separation $\Delta R_{\ell\gamma} > 0.7$, and di-lepton invariant mass > 30 GeV. The cross section is in agreement with the SM prediction. Using these $Z\gamma$ events they obtain 95% C.L. limits on each h_i^V, keeping all others fixed at their SM values. They report: $-0.083 < h_{30}^Z < 0.082$, $-0.0053 < h_{40}^Z < 0.0054$, $-0.085 < h_{30}^\gamma < 0.084$, $-0.0053 < h_{40}^\gamma < 0.0054$, for the form factor scale $\Lambda = 1.2$ TeV.

[12] Using data collected at $\sqrt{s} = 183$–208, ABDALLAH 07C select 1,877 $e^+e^- \to Z\gamma$ events with $Z \to q\overline{q}$ or $\nu\overline{\nu}$, 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on h_i^V. Each limit is derived with other parameters set to zero. They report: $-0.23 < h_1^Z < 0.23$, $-0.30 < h_3^Z < 0.16$, $-0.14 < h_1^\gamma < 0.14$, $-0.049 < h_3^\gamma < 0.044$.

[13] ACHARD 04H select 3515 $e^+e^- \to Z\gamma$ events with $Z \to q\overline{q}$ or $\nu\overline{\nu}$ at $\sqrt{s} = 189$–209 GeV to derive 95% CL limits on h_i^V. For deriving each limit the other parameters are fixed at zero. They report: $-0.153 < h_1^Z < 0.141$, $-0.087 < h_2^Z < 0.079$, $-0.220 < h_3^Z < 0.112$, $-0.068 < h_4^Z < 0.148$, $-0.057 < h_1^\gamma < 0.057$, $-0.050 < h_2^\gamma < 0.023$, $-0.059 < h_3^\gamma < 0.004$, $-0.004 < h_4^\gamma < 0.042$.

[14] ABBIENDI,G 00C study $e^+e^- \to Z\gamma$ events (with $Z \to q\overline{q}$ and $Z \to \nu\overline{\nu}$) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings: $h_1^Z = 0.000 \pm 0.100$ $(-0.190, 0.190)$, $h_2^Z = 0.000 \pm 0.068$ $(-0.128, 0.128)$, $h_3^Z = -0.074^{+0.102}_{-0.103}$ $(-0.269, 0.119)$, $h_4^Z = 0.046 \pm 0.068$ $(-0.084, 0.175)$, $h_1^\gamma = 0.000 \pm 0.061$ $(-0.115, 0.115)$, $h_2^\gamma = 0.000 \pm 0.041$ $(-0.077, 0.077)$, $h_3^\gamma = -0.080^{+0.039}_{-0.041}$ $(-0.164, -0.006)$, $h_4^\gamma = 0.064^{+0.033}_{-0.030}$ $(+0.007, +0.134)$. The results are derived assuming that only one coupling at a time is different from zero.

[15] ABBOTT 98M study $p\overline{p} \to Z\gamma + X$, with $Z \to e^+e^-$, $\mu^+\mu^-$, $\overline{\nu}\nu$ at 1.8 TeV, to obtain 95% CL limits at $\Lambda = 750$ GeV: $|h_{30}^Z| < 0.36$, $|h_{40}^Z| < 0.05$ (keeping $h_i^\gamma = 0$), and $|h_{30}^\gamma| < 0.37$, $|h_{40}^\gamma| < 0.05$ (keeping $h_i^Z = 0$). Limits on the *CP*-violating couplings are $|h_{10}^Z| < 0.36$, $|h_{20}^Z| < 0.05$ (keeping $h_i^\gamma = 0$), and $|h_{10}^\gamma| < 0.37$, $|h_{20}^\gamma| < 0.05$ (keeping $h_i^Z = 0$).

[16] ABREU 98K determine a 95% CL upper limit on $\sigma(e^+e^- \to \gamma +$ invisible particles$) < 2.5$ pb using 161 and 172 GeV data. This is used to set 95% CL limits on $|h_{30}^\gamma| < 0.8$ and $|h_{30}^Z| < 1.3$, derived at a scale $\Lambda = 1$ TeV and with $n = 3$ in the form factor representation.

f_i^V

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEL 13A]:

$$-0.28 < f_4^Z < +0.32, \qquad -0.34 < f_5^Z < +0.35,$$
$$-0.17 < f_4^\gamma < +0.19, \qquad -0.35 < f_5^\gamma < +0.32.$$

Some of the recent results from the Tevatron and LHC experiments individually surpass the combined LEP-2 results in precision (see below).

[1] SIRUNYAN 21Q measure ZZ production where both Z bosons decay in the electron or muon channel. Analyzing the four-lepton invariant mass distribution, the following limits are derived at 95% C.L. in units of 10^{-4}: $-6.6 < f_4^Z < 6.0$, $-5.5 < f_5^Z < 7.5$, $-7.8 < f_4^\gamma < 7.1$, $-6.8 < f_5^\gamma < 7.5$. This set of parameters is linearly related to a set of EFT parameters, resulting in the following limits at 95% C.L. in units of TeV^{-4}: $-2.3 < c_{\widetilde{B}W}/\Lambda^4 < 2.5$, $-1.4 < c_{WW}/\Lambda^4 < 1.2$, $-1.4 < c_{BW}/\Lambda^4 < 1.3$, $-1.2 < c_{BB}/\Lambda^4 < 1.2$.

[2] AABOUD 19AY study ZZ production in the $\ell\ell\nu\nu$ decay channel. Events with a pair of isolated high-transverse momentum charged leptons (electron pairs or muon pairs), and with large missing energy, are selected. In the data, 371 (416) di-electron (di-muon) events are found, with a total expected background of 128 ± 8 (143 ± 8) events. Analysing the transverse momentum distribution of the charged dilepton system above 150 GeV, the following 95% C.L. limits are derived in units of 10^{-3}: $-1.2 < f_4^\gamma < 1.2$, $-1.0 < f_4^Z < 1.0$, $-1.2 < f_5^\gamma < 1.2$, $-1.0 < f_5^Z < 1.0$.

[3] AABOUD 18Q study $pp \to ZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e\,2\mu$, and 4μ channels is 249, 465, and 303 respectively. Analysing the p_T spectrum of the leading Z boson, the following the following 95% C.L. limits are derived in units of 10^{-4}: $-1.8 < f_4^\gamma < 1.8$, $-1.5 < f_4^Z < 1.5$, $-1.8 < f_5^\gamma < 1.8$, $-1.5 < f_5^Z < 1.5$.

[4] SIRUNYAN 18BT study $ppZZ$ events at $\sqrt{s} = 13$ TeV with $Z \to e^+e^-$ or $Z \to \mu^+\mu^-$. The number of events observed in the $4e$, $2e2\mu$, and 4μ channels is 220, 543 and 335 respectively. Analysing the 4-lepton invariant mass spectrum, the following 95% C.L. limits are derived in units of 10^{-3}: $-1.2 < f_4^\gamma < 1.3$, $-1.2 < f_4^Z < 1.0$, $-1.2 < f_5^\gamma < 1.3$, $-1.0 < f_5^Z < 1.3$.

[5] KHACHATRYAN 15B study ZZ production in 8 TeV pp collisions. In the decay modes $ZZ \to 4e$, 4μ, $2e2\mu$, 54, 75, 148 events are observed, with an expected background of 2.2 ± 0.9, 1.2 ± 0.6, and 2.4 ± 1.0 events, respectively. Analysing the 4-lepton invariant mass spectrum in the range from 110 GeV to 1200 GeV, the following 95% C.L. limits are obtained: $|f_4^Z| < 0.004$, $|f_5^Z| < 0.004$, $|f_4^\gamma| < 0.005$, $|f_5^\gamma| < 0.005$.

[6] KHACHATRYAN 15BC use the cross section measurement of the final state $pp \to ZZ \to 2\ell2\nu$, (ℓ being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton $p_T > 45$ GeV. The reduced missing E_T is required to be > 65 GeV, which takes into account the fake missing E_T due to detector effects. The numbers of e^+e^- and $\mu^+\mu^-$ events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set: $-0.0028 < f_4^Z < 0.0032$, $-0.0037 < f_4^\gamma < 0.0033$, $-0.0029 < f_5^Z < 0.0031$, $-0.0033 < f_5^\gamma < 0.0037$. Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states $pp \to ZZ \to 2\ell2\ell'$ where ℓ and ℓ' are an electron or a muon, the best limits are $-0.0022 < f_4^Z < 0.0026$, $-0.0029 < f_4^\gamma < 0.0026$, $-0.0023 < f_5^Z < 0.0023$, $-0.0026 < f_5^\gamma < 0.0027$.

[7] AAD 13Z study ZZ production in pp collisions at $\sqrt{s} = 7$ TeV. In the $ZZ \to \ell^+\ell^-\ell'^+\ell'^-$ final state they observe a total of 66 events with an expected background of 0.9 ± 1.3. In the $ZZ \to \ell^+\ell^-\nu\nu$ final state they observe a total of 87 events with an expected background of 46.9 ± 5.2. The limits on anomalous TGCs are determined using the observed and expected numbers of these ZZ events binned in p_T^Z. The 95% C.L. are as follows: for form factor scale $\Lambda = \infty$, $-0.015 < f_4^\gamma < 0.015$, $-0.013 < f_4^Z < 0.013$, $-0.016 < f_5^\gamma < 0.015$, $-0.013 < f_5^Z < 0.013$; for form factor scale $\Lambda = 3$ TeV, $-0.022 < f_4^\gamma < 0.023$, $-0.019 < f_4^Z < 0.019$, $-0.023 < f_5^\gamma < 0.023$, $-0.020 < f_5^Z < 0.019$.

[8] CHATRCHYAN 13B study ZZ production in pp collisions and select 54 ZZ candidates in the Z decay channel with electrons or muons with an expected background of 1.4 ± 0.5 events. The resulting 95% C.L. ranges are: $-0.013 < f_4^\gamma < 0.015$, $-0.011 < f_4^Z < 0.012$, $-0.014 < f_5^\gamma < 0.014$, $-0.012 < f_5^Z < 0.012$.

[9] Using data collected in the center of mass energy range 192–209 GeV, SCHAEL 09 select 318 $e^+e^- \to ZZ$ events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits: $-0.321 < f_4^\gamma < 0.318$, $-0.534 < f_4^Z < 0.534$, $-0.724 < f_5^\gamma < 0.733$, $-1.194 < f_5^Z < 1.190$.

[10] ABAZOV 08K search for ZZ and $Z\gamma^*$ events with 1 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV in $(ee)(ee)$, $(\mu\mu)(\mu\mu)$, $(ee)(\mu\mu)$ final states requiring the lepton pair masses to be > 30 GeV. They observe 1 event, which is consistent with an expected signal of 1.71 ± 0.15 events and a background of 0.13 ± 0.03 events. From this they derive the following limits, for a form factor (Λ) value of 1.2 TeV: $-0.28 < f_{40}^Z < 0.28$, $-0.31 < f_{50}^Z < 0.29$, $-0.26 < f_{40}^\gamma < 0.26$, $-0.30 < f_{50}^\gamma < 0.28$.

[11] Using data collected at $\sqrt{s} = 183$–208 GeV, ABDALLAH 07C select 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on f_i^V. Each limit is derived with other parameters set to zero. They report: $-0.40 < f_4^Z < 0.42$, $-0.38 < f_5^Z < 0.62$, $-0.23 < f_4^\gamma < 0.25$, $-0.52 < f_5^\gamma < 0.48$.

[12] ABBIENDI 04C study ZZ production in e^+e^- collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits: $-0.45 < f_4^Z < 0.58$, $-0.94 < f_5^Z < 0.25$, $-0.32 < f_4^\gamma < 0.33$, and $-0.71 < f_5^\gamma < 0.59$.

[13] ACHARD 03D study Z-boson pair production in e^+e^- collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 01I results (656 events, expected background of 512 events), they report the following 95% CL limits: $-0.48 \le f_4^Z \le 0.46$, $-0.36 \le f_5^Z \le 1.03$, $-0.28 \le f_4^\gamma \le 0.28$, and $-0.40 \le f_5^\gamma \le 0.47$.

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised November 2015 by M.W. Grünewald (U. College Dublin) and A. Gurtu (Formerly Tata Inst.).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\tfrac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$L_6^c = -\tfrac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^{\beta}\cdot\vec{W}_{\alpha}$$
$$L_6^n = -i\tfrac{e^2}{16\Lambda^2}\, a_n\epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha}F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\tfrac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$\widetilde{L}_6^n = -i\tfrac{e^2}{16\Lambda^2}\, \widetilde{a}_n\epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha}\widetilde{F}^{\mu\nu}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately ($\widetilde{L}_6^0$ conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP ($\widetilde{L}_6^n$ violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP-violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2, where $V = W$ or Z.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}]\times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is Λ, and $g = e/sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i},\ i = 1, 2$, $f_{M,i},\ i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

The ATLAS collaboration [6], on the other hand, follows a K-matrix driven approach of Ref. 7 in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5, which account for all BSM effects.

It is the early stages in the determination of quartic couplings by the LHC experiments. It is hoped that the two collaborations, ATLAS and CMS, will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison and allow for a possible LHC combination.

a_0/Λ^2, a_c/Λ^2

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the $ZZ\gamma\gamma$ vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$
$$-0.029 < a_c^Z/\Lambda^2 < +0.039$$

Anomalous Z quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous W/Z quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the W or only to the Z or to both. Thus, results on all other AQGCs are reported together in the W listings.

[1] ABBIENDI	04L	OPAL
[2] HEISTER	04A	ALEP
[3] ACHARD	02G	L3

[1] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV^{-2}, $-0.029 < a_C^Z/\Lambda^2 < 0.029$ GeV^{-2}, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV^{-2}, $-0.052 < a_c^W/\Lambda^2 < 0.037$ GeV^{-2}.

[2] In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T_\gamma}/E_{beam} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV^{-2}, $-0.041 < a_c^Z/\Lambda^2 < 0.044$ GeV^{-2}, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV^{-2}, $-0.099 < a_c^W/\Lambda^2 < 0.093$ GeV^{-2}.

[3] ACHARD 02G study $e^+e^- \to Z\gamma\gamma \to q\overline{q}\gamma\gamma$ events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy >5 GeV and $|\cos\theta| < 0.97$, and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ($\beta < 0.73$) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the $q\overline{q}\gamma\gamma$ state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values $a_0/\Lambda^2 = 0.00^{+0.02}_{-0.01}$ GeV^{-2} and $a_C/\Lambda^2 = 0.03^{+0.01}_{-0.02}$ GeV^{-2}, where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits -0.02 GeV$^{-2} < a_0/\Lambda^2 < 0.03$ GeV^{-2} and -0.07 GeV$^{-2} < a_C/\Lambda^2 < 0.05$ GeV^{-2}.

H^0

$J = 0$

In the following H^0 refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of H^0 and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons ($H^{\pm}$ and $H^{\pm\pm}$)", respectively.

[1] SIRUNYAN 20L result of $H^0 \to \gamma\gamma$ is combined with that of $H^0 \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$ (SIRUNYAN 17AV).

[2] Combined value from $\gamma\gamma$ and $ZZ^* \to 4\ell$ final states.

[3] ATLAS and CMS data are fitted simultaneously.

[4] SIRUNYAN 20L use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H^0 \to \gamma\gamma$.

[5] SIRUNYAN 20L combine 13 TeV results with 7 and 8 TeV results (KHACHATRYAN 15AM).

[6] AABOUD 18BM use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H^0 \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[7] AABOUD 18BM use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H^0 \to \gamma\gamma$.

[8] AABOUD 18BM combine 13 TeV results with 7 and 8 TeV results. Other combined results are summarized in their Fig. 4.

[9] SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV with $H^0 \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[10] KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[11] AAD 14W use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at 8 TeV.

[12] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[13] CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[14] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV.

[15] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm}=7 TeV and 20.7 fb^{-1} at E_{cm}=8 TeV. Superseded by AAD 14W.

[16] CHATRCHYAN 13J use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 12.2 fb^{-1} at $E_{cm} = 8$ TeV.

[17] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8–5.9 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.9 σ is observed at $m_{H^0} = 126$ GeV. See also AAD 12DA.

[18] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_{H^0} = 125$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

Gauge & Higgs Boson Particle Listings

H^0

H^0 SPIN AND CP PROPERTIES

The observation of the signal in the $\gamma\gamma$ final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the CP properties is in general much more difficult since in principle the observed state could consist of any admixture of CP-even and CP-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure CP-even and pure CP-odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different CP states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a CP-even and a CP-odd state, as the cross section ratios depend in addition also on the coupling strengths of the CP-even and CP-odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of CP mixing.

[1] AAD 20N test CP invariance in H^0 production via VBF using $H^0 \to \tau\tau$ decay channel with 36.1 fb^{-1} at $E_{\rm cm} = 13$ TeV. By using the Optimal Observable method, the data constrain a parameter $\tilde{d}$, which is for the strength of CP violation in an effective field theory, to be $-0.090 \leq \tilde{d} \leq 0.035$ at 68% CL (see their Fig. 6).

[2] AAD 20Z exclude a CP-mixing angle α, $|\alpha| > 43^\circ$ at 95% CL, where $\alpha = 0$ represents the Standard Model, in 139 fb^{-1} of data at $E_{\rm cm} = 13$ TeV. The pure CP-odd structure of the top Yukawa coupling ($\alpha = 90^\circ$) is excluded at 3.9 σ.

[3] SIRUNYAN 20AS exclude the pure CP-odd structure of the top Yukawa coupling at 3.2 σ using $t\overline{t}H^0$, $H^0 \to \gamma\gamma$ in 137 fb^{-1} of data at $E_{\rm cm} = 13$ TeV. The fractional contribution of the CP-odd component $f_{CP}^{t\overline{t}H^0}$ is measured to be 0.00 ± 0.33.

[4] SIRUNYAN 19BL measure the anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. See their Tables VI and VII for anomalous HVV couplings of CP-violating and CP-conserving parameters with on- and off-shells.

[5] SIRUNYAN 19BZ constrain anomalous HVV couplings of the Higgs boson with data of 35.9 fb^{-1} at $E_{\rm cm} = 13$ TeV using Higgs boson candidates with two jets produced in VBF, ggF, and VH that decay to $\tau\tau$. See their Table 2 and Fig. 10, which show 68% CL and 95% CL intervals. Combining those with the $H^0 \to 4\ell$ (SIRUNYAN 19BL, on-shell scenario), results shown in their Tables 3, 4, and Fig. 11 are obtained. A CP-violating parameter is set to be $f_{a3}\cos(\phi_{a3}) = (0.00 \pm 0.27) \times 10^{-3}$ and CP-conserving parameters are $f_{a2}\cos(\phi_{a2}) = (0.08^{+1.04}_{-0.21}) \times 10^{-3}$, $f_{\Lambda 1}\cos(\phi_{\Lambda 1}) = (0.00^{+0.53}_{-0.09}) \times 10^{-3}$, and $f_{\Lambda 1}^{Z\gamma}\cos(\phi_{\Lambda 1}^{Z\gamma}) = (0.0^{+1.1}_{-1.3}) \times 10^{-3}$.

[6] AABOUD 18AJ study the tensor structure of the Higgs boson couplings using an effective Lagrangian using 36.1 fb^{-1} of pp collision data at $E_{\rm cm} = 13$ TeV. Constraints are set on the non-Standard-Model CP-even and CP-odd couplings to Z bosons and on the CP-odd coupling to gluons. See their Figs. 9 and 10, and Tables 10 and 11.

[7] SIRUNYAN 17AM constrain anomalous couplings of the Higgs boson with 5.1 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV, 19.7 fb^{-1} at $E_{\rm cm} = 8$ TeV, and 38.6 fb^{-1} at $E_{\rm cm} = 13$ TeV. See their Table 3 and Fig. 3, which show 68% CL and 95% CL intervals. A CP violation parameter f_{a3} is set to be $f_{a3}\cos(\phi_{a3}) = [-0.38, 0.46]$ at 95% CL ($\phi_{a3} = 0$ or π).

[8] AAD 16 study $H^0 \to \gamma\gamma$ with an effective Lagrangian including CP even and odd terms in 20.3 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.

[9] AAD 16BL study VBF $H^0 \to \tau\tau$ with an effective Lagrangian including a CP odd term in 20.3 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. The measurement is consistent with the expectation of the Standard Model. The CP-mixing parameter $\tilde{d}$ (a dimensionless coupling $\tilde{d} = -(m_W^2/\Lambda^2) f_{\widetilde{W}W}$) is constrained to the interval of $(-0.11, 0.05)$ at 68% CL under the assumption of $\tilde{d} = \tilde{d}_B$.

[10] KHACHATRYAN 16AB search for anomalous pseudoscalar couplings of the Higgs boson to W and Z with 18.9 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. See their Table 5 and Figs 5 and 6 for limits on possible anomalous pseudoscalar coupling parameters.

[11] AAD 15AX compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 20.3 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV, using the process $H^0 \to WW^* \to e\nu\mu\nu$. 2^+ hypotheses are excluded at 84.5–99.4%CL, 0^- at 96.5%CL, 0^+ (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible CP mixture parameters.

[12] AAD 15CI compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 4.5 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV and 20.3 fb^{-1} at $E_{\rm cm} = 8$ TeV, using the processes $H^0 \to ZZ^* \to 4\ell$. $H^0 \to \gamma\gamma$ and combine with AAD 15AX data. 0^+ (field strength coupling), 0^- and several 2^+ hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible CP mixture parameters.

[13] AALTONEN 15 combine AALTONEN 15B and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a 0^- and a 2^+ state. Assuming the SM event rate, the $J^{CP} = 0^-$ (2^+) hypothesis is excluded at the 5.0σ (4.9σ) level.

[14] AALTONEN 15B compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 9.45 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV, using the processes $ZH^0 \to \ell\ell b\overline{b}$, $WH^0 \to \ell\nu b\overline{b}$, and $ZH^0 \to \nu\nu b\overline{b}$. Bounds on the production rates of 0^- and 2^+ (graviton-like) states are set, see their tables II and III.

[15] KHACHATRYAN 15Y compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in up to 5.1 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV and up to 19.7 fb^{-1} at $E_{\rm cm} = 8$ TeV, using the processes $H^0 \to 4\ell$, $H^0 \to WW^*$, and $H^0 \to \gamma\gamma$. 0^- is excluded at 99.98% CL, and several 2^+ hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.999% CL in ZZ^* and WW^* modes. Limits on anomalous couplings and several cross section fractions, treating the case of CP-mixed states, are also given.

[16] ABAZOV 14F compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV. They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states $ZH \to \ell\ell b\overline{b}$, $WH \to \ell\nu b\overline{b}$, and $ZH \to \nu\nu b\overline{b}$. The 0^- (2^+) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fractions $f_X = \sigma_X/(\sigma_{0^+} + \sigma_X)$ are considered, where $X = 0^-, 2^+$. Values for f_{0^-} (f_{2^+}) above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.

[17] CHATRCHYAN 14AA compare the $J^{CP} = 0^+$ Standard Model assignment with various J^{CP} hypotheses in 5.1 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV and 19.7 fb^{-1} at $E_{\rm cm} = 8$ TeV. $J^{CP} = 0^-$ and $1^\pm$ hypotheses are excluded at 99% CL, and several $J = 2$ hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fraction $f_{a3} = |a_3|^2\sigma_3 / (|a_1|^2\sigma_1 + |a_2|^2\sigma_2 + |a_3|^2\sigma_3)$ is considered, where the case $a_3 = 1$, $a_1 = a_2 = 0$ corresponds to a pure CP-odd state. Assuming $a_2 = 0$, a value for f_{a3} above 0.51 is excluded at 95% CL.

[18] CHATRCHYAN 14G compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in 4.9 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV and 19.4 fb^{-1} at $E_{\rm cm} = 8$ TeV. Varying the fraction of the production of the 2^+ state via gg and $q\overline{q}$, 2^+ hypotheses are disfavored at CL between 83.7 and 99.8%. The 0^- hypothesis is disfavored against 0^+ at the 65.3% CL.

[19] KHACHATRYAN 14P compare the $J^{CP} = 0^+$ Standard Model assignment with a 2^+ (graviton-like coupling) hypothesis in 5.1 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV and 19.7 fb^{-1} at $E_{\rm cm} = 8$ TeV. Varying the fraction of the production of the 2^+ state via gg and $q\overline{q}$, 2^+ hypotheses are disfavored at CL between 71 and 94%.

[20] AAD 13AJ compare the spin 0, CP-even hypothesis with specific alternative hypotheses of spin 0, CP-odd, spin 1, CP-even and CP-odd, and spin 2, CP-even models using the Higgs boson decays $H \to \gamma\gamma$, $H \to ZZ^* \to 4\ell$ and $H \to WW^* \to \ell\nu\ell\nu$ and combinations thereof. The data are compatible with the spin 0, CP-even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.

[21] CHATRCHYAN 13J study angular distributions of the lepton pairs in the ZZ^* channel where both Z bosons decay to e or μ pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure CP-even hypothesis, while the pure CP-odd hypothesis is disfavored.

H^0 DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to ZZ^* and interference effects between signal and background in Higgs decays to $\gamma\gamma$ can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to ZZ^* rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

[1] SIRUNYAN 19BL measure the width and anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. The total width for the SM-like couplings is measured to be also [0.08, 9.16] MeV with 95% CL, assuming SM-like couplings for on- and off-shells (see their Table VIII). Constraints on the total width for anomalous HVV interaction cases are found in their Table IX. See their Table X for the Higgs boson signal strength in the off-shell region.

[2] AABOUD 18BP use 36.1 fb^{-1} at $E_{cm} = 13$ TeV. An observed upper limit on the off-shell Higgs signal strength of 3.8 is obtained at 95% CL using off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ decay channels ($\ell = e,\ \mu$). Combining with the on-shell signal strength measurements, the quoted upper limit on the Higgs boson total width is obtained, assuming the ratios of the relevant Higgs-boson couplings to the SM predictions are constant with energy from on-shell production to the high-mass range.

[3] SIRUNYAN 17AV obtain an upper limit on the width from the $m_{4\ell}$ distribution in $ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays. Data of 35.9 fb^{-1} pp collisions at $E_{cm} = 13$ TeV is used. The expected limit is 1.60 GeV.

[4] KHACHATRYAN 16BA derive constraints on the total width from comparing $WW^{(*)}$ production via on-shell and off-shell H^0 using 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.4 fb^{-1} at 8 TeV.

[5] KHACHATRYAN 16BA combine the $WW^{(*)}$ result with $ZZ^{(*)}$ results of KHACHATRYAN 15BA and KHACHATRYAN 14D.

[6] AAD 15BE derive constraints on the total width from comparing $ZZ^{(*)}$ and $WW^{(*)}$ production via on-shell and off-shell H^0 using 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The K factor for the background processes is assumed to be equal to that for the signal.

[7] KHACHATRYAN 15AM combine $\gamma\gamma$ and $ZZ^* \to 4\ell$ results. The expected limit is 2.3 GeV.

[8] KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance $\tau < 1.9 \times 10^{-13}$ s. 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at 8 TeV are used.

[9] KHACHATRYAN 15BA derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell H^0 with an unconstrained anomalous coupling. 4ℓ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV are used.

[10] AAD 14W use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at 8 TeV. The expected limit is 6.2 GeV.

[11] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The expected limit is 2.8 GeV.

[12] KHACHATRYAN 14D derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell H^0. 4ℓ and $\ell\ell\nu\nu$ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV are used.

[13] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The expected limit is 3.1 GeV.

[1] SIRUNYAN 21Z search for $H^0 \to \mu\tau$ in 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The limit constrains the $Y_{\mu\tau}$ Yukawa coupling to $\sqrt{|Y_{\mu\tau}|^2+|Y_{\tau\mu}|^2} < 1.11\times10^{-3}$ at 95% CL (see their Fig. 8).
[2] AAD 20A search for $H^0 \to \mu\tau$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The limit constrains the $Y_{\mu\tau}$ Yukawa coupling to $\sqrt{|Y_{\mu\tau}|^2+|Y_{\tau\mu}|^2} < 1.5\times10^{-3}$ at 95% CL (see their Fig. 5).
[3] AAIJ 18AM search for $H^0 \to \mu\tau$ in 2.0 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit constrains the $Y_{\mu\tau}$ Yukawa coupling to $\sqrt{|Y_{\mu\tau}|^2+|Y_{\tau\mu}|^2} < 1.7\times10^{-2}$ at 95% CL assuming SM production cross sections.
[4] SIRUNYAN 18BH search for $H^0 \to \mu\tau$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The limit constrains the $Y_{\mu\tau}$ Yukawa coupling to $\sqrt{|Y_{\mu\tau}|^2+|Y_{\tau\mu}|^2} < 1.43\times10^{-3}$ at 95% CL (see their Fig. 10).
[5] AAD 17 search for $H^0 \to \mu\tau$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV.
[6] KHACHATRYAN 15Q search for $H^0 \to \mu\tau$ with τ decaying electronically or hadronically in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The fit gives $B(H^0 \to \mu\tau) = (0.84^{+0.39}_{-0.37})\%$ with a significance of 2.4 σ.

[1] AABOUD 19AL combine results of 7, 8 (AAD 15CX), and 13 TeV for H^0 decaying to invisible final states.
[2] SIRUNYAN 19BO combine 13 TeV 35.9 fb^{-1} results with 7, 8, 13 TeV (KHACHATRYAN 17F) for H^0 decaying to invisible final states. The quoted limit on the branching ratio is given for m_{H^0} = 125.09 GeV and assumes the Standard Model production rates. The branching ratio is obtained to be 0.05 ± 0.03 (stat) ± 0.07(syst).
[3] AAD 21F search for an invisibly decaying Higgs boson with an energetic jet ($p_T > 150$ GeV) and missing transverse momentum (> 200 GeV) in 139 fb^{-1} at E_{cm} = 13 TeV. The quoted limit on the branching ratio is given for m_{H^0} = 125 GeV.
[4] SIRUNYAN 21A search for H^0 decaying to invisible final states associated with a Z decaying $ee/\mu\mu$ using 137 fb^{-1} at 13 TeV. The limit is obtained for m_{H^0} = 125 GeV and assuming the SM ZH^0 production cross section.
[5] TUMASYAN 21D search for H^0 decaying to invisible final states associated with an energetic jet or a V, $V \to q\overline{q}$ using 101 fb^{-1} at 13 TeV and the result is combined with SIRUNYAN 18S.
[6] AABOUD 19AI search for $pp \to qqH^0X$ (VBF) with H^0 decaying to invisible final states using 36.1 fb^{-1} of data. The quoted limit on the branching ratio is given for m_{H^0} = 125 GeV and assumes the Standard Model rates for VBF and gluon-fusion production.
[7] AABOUD 19AL combine results of H^0 decaying to invisible final states with VBF(AABOUD 19AI), ZH, and WH productions (AABOUD 18, AABOUD 18CA), which use 36.1 fb^{-1} of data at 13 TeV. The quoted limit is given for m_{H^0} = 125 GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[8] SIRUNYAN 19AT perform a combined fit with visible decay using 35.9 fb^{-1} of data at 13 TeV.

[9] SIRUNYAN 19BO search for $pp \to qqH^0X$ (VBF) with H^0 decaying to invisible final states using 35.9 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates.

[10] SIRUNYAN 19BO combine the VBF channel with results of other 13 TeV analyses: SIRUNYAN 18BV and SIRUNYAN 18S. The quoted limit on the branching ratio is given for $m_{H^0} = 125.09$ GeV and assumes the Standard Model production rates.

[11] AABOUD 18 search for $pp \to H^0ZX$, $Z \to ee$, $\mu\mu$ with H^0 decaying to invisible final states in 36.1 fb^{-1} at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for H^0Z production.

[12] AABOUD 18CA search for H^0 decaying to invisible final states using WH, and ZH productions, where W and Z hadronically decay. The data of 36.1 fb^{-1} at $E_{cm} = 13$ TeV is used. The quoted limit assumes SM production cross sections with combining the contributions from WH, ZH, ggF and VBF production modes.

[13] SIRUNYAN 18BV search for H^0 decaying to invisible final states associated with a Z, $Z \to \ell\ell$ using 35.9 fb^{-1} at 13 TeV.The limit is obtained for $m_{H^0} = 125$ GeV and assuming the SM ZH^0 production cross section.

[14] SIRUNYAN 18S search for H^0 decaying to invisible final states associated with an energetic jet or a V, $V \to q\overline{q}$ using 35.9 fb^{-1} at 13 TeV.

[15] AABOUD 17BD search for H^0 decaying to invisible final states with ≥ 1 jet and VBF events using 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. A cross-section ratio R^{miss} is used in the measurement. The quoted limit is given for $m_{H^0} = 125$ GeV.

[16] KHACHATRYAN 17F search for H^0 decaying to invisible final states with gluon fusion, VBF, ZH, and WH productions using 2.3 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV. The quoted limit is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[17] AAD 16AF search for $pp \to qqH^0X$ (VBF) with H^0 decaying to invisible final states in 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[18] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The branching fraction of decays into BSM particles that are invisible or into undetected decay modes is measured for $m_{H^0} = 125.09$ GeV.

[19] AAD 15BD search for $pp \to H^0WX$ and $pp \to H^0ZX$ with W or Z decaying hadronically and H^0 decaying to invisible final states using data at $E_{cm} = 8$ TeV. The quoted limit is given for $m_{H^0} = 125$ GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from H^0W, H^0Z and the gluon-fusion process.

[20] AAD 15CX search for H^0 decaying to invisible final states with VBF, ZH, and WH productions using 20.3 fb^{-1} at 8 TeV, and 4.7 fb^{-1} at 7 TeV. The quoted limit is given for $m_{H^0} = 125.36$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions. The upper limit is improved to 0.23 by adding the measured visible decay rates.

[21] AAD 14O search for $pp \to H^0ZX$, $Z \to \ell\ell$, with H^0 decaying to invisible final states in 4.5 fb^{-1} at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125.5$ GeV and assumes the Standard Model rate for H^0Z production.

[22] CHATRCHYAN 14B search for $pp \to H^0ZX$, $Z \to \ell\ell$ and $Z \to b\overline{b}$, and also $pp \to qqH^0X$ with H^0 decaying to invisible final states using data at $E_{cm} = 7$ and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from H^0Z and qqH^0. It is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rates for the two production processes.

[23] CHATRCHYAN 14B search for $pp \to H^0ZX$ with H^0 decaying to invisible final states and $Z \to \ell\ell$ in 4.9 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV, and also with $Z \to b\overline{b}$ in 18.9 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for H^0Z production.

[24] CHATRCHYAN 14B search for $pp \to qqH^0X$ (vector boson fusion) with H^0 decaying to invisible final states in 19.5 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV and assumes the Standard Model rate for qqH^0 production.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
<0.029	95	1,2 SIRUNYAN	21L	CMS	VBF, H^0Z, $H^0 \to \gamma$ + invisible, 13 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.035	95	[1] SIRUNYAN	21L	CMS	VBF, $H^0 \to \gamma$+ invisible, 13 TeV
<0.046	95	[3] SIRUNYAN	19CG	CMS	$pp \to H^0Z$, $H^0 \to \gamma$+ invisible, $Z \to \ell\ell$, 13 TeV

[1] SIRUNYAN 21L search for H^0 decaying to an invisible final state plus a γ in the VBF production using 130 fb^{-1} data at $E_{cm} = 13$ TeV. The invisible state is called a dark photon. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV assuming the Standard Model rates.

[2] The result of the VBF production is combined with the $pp \to H^0Z$ result (SIRUNYAN 19CG).

[3] SIRUNYAN 19CG search for $pp \to H^0Z$, $Z \to ee$, $\mu\mu$ with H^0 decaying to invisible final states plus a γ in 137 fb^{-1} at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_{H^0} = 125$ GeV assuming the Standard Model rate for H^0Z production and is obtained in the context of a theoretical model, where the undetected (invisible) particle is massless.

H^0 SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The H^0 signal strength in a particular final state xx is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value, $\sigma \cdot B(H^0 \to xx) / (\sigma \cdot B(H^0 \to xx))_{SM}$, for the specified mass value of H^0. For the SM predictions, see DITTMAIER 11, DITTMAIER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

[1] AAD 20 combine results of up to 79.8 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_{H^0} = 125.09$ GeV: $\gamma\gamma$, ZZ^*, WW^*, $\tau\tau$, $b\overline{b}$, $\mu\mu$, invisible, and off-shell analyses (see their Table I). The signal strengths for individual production processes are 1.04 ± 0.09 for gluon fusion, $1.21^{+0.24}_{-0.22}$ for vector boson fusion, $1.30^{+0.40}_{-0.38}$ for WH^0 production, $1.05^{+0.31}_{-0.29}$ for ZH^0 production, and $1.21^{+0.26}_{-0.24}$ for $t\overline{t}H^0 + tH^0$ production (see their Fig. 2 and Table IV). Several results with the simplified template cross section and κ-frameworks are presented: see their Figs. 9–11, Figs 20, 21 and Table VIII for stage-1 simplified template cross sections, their Figs. 12–17 and Tables X–XII for the κ-framework.

[2] SIRUNYAN 19AT combine results of 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_{H^0} = 125.09$ GeV. The signal strengths for individual production processes are $1.22^{+0.14}_{-0.12}$ for gluon fusion, $0.73^{+0.30}_{-0.27}$ for vector boson fusion, $2.18^{+0.58}_{-0.55}$ for WH^0 production, $0.87^{+0.44}_{-0.42}$ for ZH^0 production, and $1.18^{+0.30}_{-0.27}$ for $t\overline{t}H^0$ production. Several results with the simplified template cross section and κ-frameworks are presented: see their Fig. 8 and Table 5 for stage-0 simplified template cross sections, their Figs. 9–18 and Tables 7–11 for the κ-framework.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.03^{+0.16}_{-0.14}$ for gluon fusion, $1.18^{+0.25}_{-0.23}$ for vector boson fusion, $0.89^{+0.40}_{-0.38}$ for WH^0 production, $0.79^{+0.38}_{-0.36}$ for ZH^0 production, and $2.3^{+0.7}_{-0.6}$ for $t\overline{t}H^0$ production.

[4] AAD 16AN: The uncertainties represent statistics, experimental systematics, theory systematics on the background, and theory systematics on the signal. The quoted signal strengths are given for $m_{H^0} = 125.09$ GeV. In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[6] SIRUNYAN 19BA measure differential cross sections for the Higgs boson transverse momentum, the number of jets, the rapidity of the Higgs boson and the transverse momentum of the leading jet using 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV with $H^0 \to \gamma\gamma$, $H^0 \to ZZ^*$, and $H^0 \to b\overline{b}$. The total cross section for Higgs boson production is measured to be $61.1 \pm 6.0 \pm 3.7$ pb using $H^0 \to \gamma\gamma$ and $H^0 \to ZZ^*$ channels. Several coupling measurements in the κ-framework are performed.

[7] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are $1.23 \pm 0.14^{+0.09}_{-0.08}{}^{+0.16}_{-0.12}$ for gluon fusion, $1.23^{+0.28}_{-0.27}{}^{+0.13}_{-0.12}{}^{+0.11}_{-0.09}$ for vector boson fusion, $0.80^{+0.31}_{-0.30} \pm 0.17^{+0.10}_{-0.05}$ for W/ZH^0 production, and $1.81^{+0.52}_{-0.50}{}^{+0.58}_{-0.55}{}^{+0.31}_{-0.12}$ for $t\overline{t}H^0$ production. The quoted signal strengths are given for $m_{H^0} = 125.36$ GeV.

[8] AAD 15P measure total and differential cross sections of the process $pp \to H^0X$ at $E_{cm} = 8$ TeV with 20.3 fb^{-1}. $\gamma\gamma$ and 4ℓ final states are used. $\sigma(pp \to H^0X) = 33.0 \pm 5.3 \pm 1.6$ pb is given. See their Figs. 2 and 3 for data on differential cross sections.

[9] KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 19.7 fb^{-1} at E_{cm} = 8 TeV. The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of $0.85^{+0.19}_{-0.16}$ for gluon fusion, $1.16^{+0.37}_{-0.34}$ for vector boson fusion, $0.92^{+0.38}_{-0.36}$ for WH^0, ZH^0 production, and $2.90^{+1.08}_{-0.94}$ for $t\overline{t}H^0$ production.

[10] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.7 fb^{-1} at E_{cm} = 8 TeV. The combined signal strength is based on the $\gamma\gamma$, $ZZ^* \to 4\ell$, and $WW^* \to \ell\nu\ell\nu$ channels. The quoted signal strength is given for m_{H^0} = 125.5 GeV. Reported statistical error value modified following private communication with the experiment.

[11] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[12] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[13] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.8–5.9 fb^{-1} at E_{cm} = 8 TeV. An excess of events over background with a local significance of 5.9 σ is observed at m_{H^0} = 126 GeV. The quoted signal strengths are given for m_{H^0} = 126 GeV. See also AAD 12DA.

[14] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.1–5.3 fb^{-1} at E_{cm} = 8 TeV. An excess of events over background with a local significance of 5.0 σ is observed at about m_{H^0} = 125 GeV. The combined signal strength is based on the $\gamma\gamma$, ZZ^*, WW^*, $\tau^+\tau^-$, and $b\overline{b}$ channels. The quoted signal strength is given for m_{H^0} = 125.5 GeV. See also CHATRCHYAN 13Y.

[1] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[2] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are 0.84 ± 0.17 for gluon fusion, 1.2 ± 0.4 for vector boson fusion, $1.6^{+1.2}_{-1.0}$ for WH^0 production, $5.9^{+2.6}_{-2.2}$ for ZH^0 production, and $5.0^{+1.8}_{-1.7}$ for $t\overline{t}H^0$ production.

[3] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_{H^0} = 125.09 GeV.

[4] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[5] AABOUD 19F measure cross-sections times the $H^0 \to WW^*$ branching fraction in the $H^0 \to WW^* \to e\nu\mu\nu$ channel using 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV: $\sigma_{ggF}\times B(H^0 \to WW^*) = 11.4^{+1.2+1.8}_{-1.1-1.7}$ pb and $\sigma_{VBF}\times B(H^0 \to WW^*) = 0.50^{+0.24}_{-0.22} \pm 0.17$ pb.

[6] AAD 19A use 36.1 fb^{-1} data at 13 TeV. The cross section times branching fraction values are measured to be $0.67^{+0.31+0.18}_{-0.27-0.14}$ pb for WH^0, $H^0 \to WW^*$ and $0.54^{+0.31+0.15}_{-0.24-0.07}$ pb for ZH^0, $H^0 \to WW^*$.

[7] SIRUNYAN 19AX measure the signal strengths, cross sections and so on using gluon fusion, VBF and VH^0 production processes with 35.9 fb^{-1} of data. The quoted signal strength is given for m_{H^0} = 125.09 GeV. Signal strengths for each production process is found in their Fig. 9. Measured cross sections and ratios to the SM predictions in the stage-0 simplified template cross section framework are shown in their Fig. 10. $\kappa_F = 1.52^{+0.48}_{-0.41}$ and $\kappa_V = 1.10 \pm 0.08$ are obtained (see their Fig. 11 (right)).

[8] AAD 16AO measure fiducial total and differential cross sections of gluon fusion process at E_{cm} = 8 TeV with 20.3 fb^{-1} using $H^0 \to WW^* \to e\nu\mu\nu$. The measured fiducial total cross section is 36.0 ± 9.7 fb in their fiducial region (Table 7). See their Fig. 6 for fiducial differential cross sections. The results are given for m_{H^0} = 125 GeV.

[9] AAD 16K use up to 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.36 GeV.

[10] AAD 15AA use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The signal strength for the gluon fusion and vector boson fusion mode is $1.02 \pm 0.19^{+0.22}_{-0.18}$ and $1.27^{+0.44+0.30}_{-0.40-0.21}$, respectively. The quoted signal strengths are given for m_{H^0} = 125.36 GeV.

[11] AAD 15AQ use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.36 GeV.

[12] AAD 15AQ combine their result on W/ZH^0 production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for m_{H^0} = 125.36 GeV.

[13] CHATRCHYAN 14G use 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.4 fb^{-1} at E_{cm} = 8 TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for m_{H^0} = 125.6 GeV.

[14] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.7 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.5 GeV. Superseded by AAD 15AA.

[15] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[16] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[17] AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.8 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strengths are given for m_{H^0} = 126 GeV. See also AAD 12DA.

[18] CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.1 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.5 GeV. See also CHATRCHYAN 13Y.

[1] SIRUNYAN 21S measure cross sections with the $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) channel using 137 fb^{-1} data at E_{cm} = 13 TeV. Results are given for m_{H^0} = 125.38 GeV. The signal strengths for individual production processes in their Table 4. Cross sections are given in their Table 6 and Fig. 14, which are based on the simplified template cross section framework (reduced stage-1.2).

[2] AAD 20AQ perform analyses using $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 139 fb^{-1} at E_{cm} = 13 TeV. Results are given for m_{H^0} = 125 GeV.

[3] AAD 20AQ measured the inclusive cross section times branching ratio for $H^0 \to ZZ^*$ decay ($|y(H^0)| < 2.5$) to be 1.34 ± 0.12 pb (with 1.33 ± 0.08 pb expected in the SM).

[4] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are $1.13^{+0.34}_{-0.31}$ for gluon fusion and $0.1^{+1.1}_{-0.6}$ for vector boson fusion.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_{H^0} = 125.09 GeV.

[6] SIRUNYAN 21AE obtains constraints on anomalous couplings to vector bosons (W, Z, and gluon) and top quark using $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 137 fb^{-1} at $E_{cm} = 13$ TeV. Their Table 5 and Figs 14–17 show (effective) couplings to gluon and top with combining gluon fusion, $t\bar{t}H^0$ and tH^0 production channels and the result of $t\bar{t}H^0$, $H^0 \to \gamma\gamma$ (SIRUNYAN 20AS). Their Tables 6–9 and Figs 18–22 show couplings to W and Z for different assumptions and bases (Higgs and Warsaw).

[7] AAD 20AQ present several results for the channel $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with the simplified template cross section with κ-frameworks and the effective field theory (EFT) approach; see their Table 8 and Fig. 10 for simplified template cross sections. $\kappa_V = 1.02 \pm 0.06$ and $\kappa_F = 0.88 \pm 0.16$ are obtained, see their Fig. 12 for the κ-framework. See their Tables 9 and 10 and Figs. 16–18 for the EFT-framework.

[8] AAD 20BA measure the cross section for $pp \to H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 139 fb^{-1} at $E_{cm} = 13$ TeV. They give $\sigma \cdot B = 3.28 \pm 0.30 \pm 0.11$ fb in their fiducial region, where 3.41 ± 0.18 fb is expected in the Standard Model for $m_{H^0} = 125$ GeV. Various differential cross sections are also given; see their Figs. 19-39. Constraints on Yukawa couplings for bottom and charm quarks are given in their Table 9 and Fig. 41.

[9] AABOUD 19N measure the spectrum of the four-lepton invariant mass $m_{4\ell}$ ($\ell = e$ or μ) using 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from 180 GeV $< m_{4\ell} <$ 1200 GeV.

[10] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[11] AABOUD 18AJ perform analyses using $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 36.1 fb^{-1} at $E_{cm} = 13$ TeV. Results are given for $m_{H^0} = 125.09$ GeV. The inclusive cross section times branching ratio for $H^0 \to ZZ^*$ decay ($|\eta(H^0)| < 2.5$) is measured to be $1.73^{+0.26}_{-0.24}$ pb (with $1.34^{+0.09}_{-0.09}$ pb expected in the SM).

[12] AABOUD 18BP measure an off-shell Higgs boson production using $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ ($\ell = e,\ \mu$) decay channels with 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from a combination of these two channels, where 220 GeV $< m_{4\ell} <$ 2000 GeV for $ZZ \to 4\ell$ and 250 GeV $< m_T^{ZZ} <$ 2000 GeV for $ZZ \to 2\ell 2\nu$ (m_T^{ZZ} is defined in their Section 5). See their Table 2 for each measurement.

[13] SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength, obtained from the analysis of $H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays, is given for $m_{H^0} = 125.09$ GeV. The signal strengths for different production modes are given in their Table 3. The fiducial and differential cross sections are shown in their Fig. 10.

[14] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.

[15] KHACHATRYAN 16AR use data of 5.1 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at 8 TeV. The fiducial cross sections for the production of 4 leptons via $H^0 \to 4\ell$ decays are measured to be $0.56^{+0.67}_{-0.44}{}^{+0.21}_{-0.06}$ fb at 7 TeV and $1.11^{+0.41}_{-0.35}{}^{+0.14}_{-0.10}$ fb at 8 TeV in their fiducial region (Table 2). The differential cross sections at $E_{cm} = 8$ TeV are also shown in Figs. 4 and 5. The results are given for $m_{H^0} = 125$ GeV.

[16] AAD 15F use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV. The signal strength for the gluon fusion production mode is $1.66^{+0.45}_{-0.41}{}^{+0.25}_{-0.15}$, while the signal strength for the vector boson fusion production mode is $0.26^{+1.60}_{-0.91}{}^{+0.36}_{-0.23}$.

[17] AAD 14AR measure the cross section for $pp \to H^0 \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 20.3fb^{-1} at $E_{cm} = 8$ TeV. They give $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08$ fbin their fiducial region, where 1.30 ± 0.13 fb is expected in the Standard Model for m_{H^0}= 125.4 GeV. Various differential cross sections are also given; see their Fig. 2.

[18] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.6$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $0.80^{+0.46}_{-0.36}$, while the signal strength for the vector boson fusion and WH^0, ZH^0 production mode is $1.7^{+2.2}_{-2.1}$.

[19] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.

[20] CHATRCHYAN 13J obtain results based on $ZZ \to 4\ell$ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 12.2 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.8$ GeV. Superseded by CHATRCHYAN 14AA.

[21] AAD 12AI obtain results based on 4.7–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_{H^0} = 126$ GeV. See also AAD 12DA.

[22] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_{H^0} = 125$ GeV. The quoted signal strengths are given for $m_{H^0} = 125.5$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

[1] SIRUNYAN 21O measures cross sections and couplings with the $H^0 \to \gamma\gamma$ channel using 137 fb^{-1} data at $E_{cm} = 13$ TeV. Results are given for $m_{H^0} = 125.38$ GeV. The signal strengths for individual production processes are given in their Fig. 16. Cross sections are given in their Tables 12 and 13 and Figs. 18 and 20, which are based on the simplified template cross section framework (reduced stage-1.2). Results in the κ-framework are given in their Fig. 22.

[2] AABOUD 18BO use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The signal strengths for the individual production modes are: $0.81^{+0.19}_{-0.18}$ for gluon fusion, $2.0^{+0.6}_{-0.5}$ for vector boson fusion, $0.7^{+0.9}_{-0.8}$ for VH^0 production ($V = W, Z$), and 0.5 ± 0.6 for $t\bar{t}H^0$ and tH^0 production. Other measurements of cross sections and couplings are summarized in their Section 10. The quoted values are given for $m_{H^0} = 125.09$ GeV.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.10^{+0.23}_{-0.22}$ for gluon fusion, 1.3 ± 0.5 for vector boson fusion, $0.5^{+1.3}_{-1.2}$ for WH^0 production, $0.5^{+3.0}_{-2.5}$ for ZH^0 production, and $2.2^{+1.6}_{-1.3}$ for $t\bar{t}H^0$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[6] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[7] SIRUNYAN 19L measure fiducial and differential cross sections of the process $pp \to H^0 \to \gamma\gamma$ at $E_{cm} = 13$ TeV with 35.9 fb^{-1}. See their Figs. 4–11.

[8] SIRUNYAN 18DS use 35.9 fb^{-1} of $pp \to H^0$ collisions with $H^0 \to \gamma\gamma$ at $E_{cm} = 13$ TeV. The Higgs mass is floated in the measurement of a signal strength. The result is $1.18^{+0.12}_{-0.11}(\text{stat.})^{+0.09}_{-0.07}(\text{syst.})^{+0.07}_{-0.06}(\text{theory})$, which is largely insensitive to the Higgs mass around 125 GeV.

[9] KHACHATRYAN 16G measure fiducial and differential cross sections of the process $pp \to H^0 X$, $H^0 \to \gamma\gamma$ at $E_{cm} = 8$ TeV with 19.7 fb^{-1}. See their Figs. 4–6 and Table 1 for data.

[10] AAD 14BC use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 125.4$ GeV. The signal strengths for the individual production modes are: 1.32 ± 0.38 for gluon fusion, 0.8 ± 0.7 for vector boson fusion, 1.0 ± 1.6 for WH^0 production, $0.1^{+3.7}_{-0.1}$ for ZH^0 production, and $1.6^{+2.7}_{-1.8}$ for $t\bar{t}H^0$ production.

[11] AAD 14BJ measure fiducial and differential cross sections of the process $pp \to H^0 X$, $H^0 \to \gamma\gamma$ at $E_{cm} = 8$ TeV with 20.3 fb^{-1}. See their Table 3 and Figs. 3–12 for data.

[12] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_{H^0} = 124.7$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $1.13^{+0.37}_{-0.31}$, while the signal strength for the vector boson fusion and WH^0, ZH^0 production mode is $1.16^{+0.63}_{-0.58}$.

[13] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.5$ GeV.

[14] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[15] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[16] AAD 12AI obtain results based on 4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.9 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_{H^0} = 126$ GeV. See also AAD 12DA.

[17] CHATRCHYAN 12N obtain results based on 5.1 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.3 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_{H^0}=125.5 GeV. See also CHATRCHYAN 13Y.

<110	95	[2] AABOUD	18M	ATLS	pp, 13 TeV

[1] SIRUNYAN 20AE use 35.9 fb^{-1} at of pp collisions at $E_{cm} = 13$ TeV. The measured best fit value of $\sigma(pp \to VH^0) \cdot B(H^0 \to c\overline{c})$ is $2.40^{+1.12}_{-1.11}{}^{+0.65}_{-0.61}$ pb (equivalent to < 4.5 pb at 95% CL upper limit, i.e. 70 times the standard model), where V is $W \to \ell\nu$, $Z \to \ell\ell$, or $Z \to \nu\nu$ ($\ell = e,\ \mu$). The quoted values are given for $m_{H^0} = 125$ GeV.

[2] AABOUD 18M use 36.1 fb^{-1} at of pp collisions at $E_{cm} = 13$ TeV. The upper limit on $\sigma(pp \to ZH^0) \cdot B(H^0 \to c\overline{c})$ is 2.7 pb at 95% CL. This corresponds to 110 times the standard model. The quoted values are given for $m_{H^0} = 125$ GeV.

[1] AAD 21AB search for VH^0, $H^0 \to b\overline{b}$ ($V = W$, Z) using 139 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The results are given for $m_{H^0} = 125$ GeV. Cross sections are given in their Table 13 and Fig. 7, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 9.

[2] AAD 21AJ present measurements of $H^0 \to b\overline{b}$ in the VBF production mode. The inclusive VBF cross sections with and without the branching ratio of $H^0 \to b\overline{b}$ are $2.07 \pm 0.70^{+0.46}_{-0.37}$ fb and $3.56 \pm 1.21^{+0.80}_{-0.64}$ fb, respectively. The latter is obtained assuming the SM value of B($H^0 \to b\overline{b}$) = 0.5809 and $m_{H^0} = 125$ GeV.

[3] SIRUNYAN 18DB search for VH^0, $H^0 \to b\overline{b}$ ($V = W$, Z) using 77.2 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 4.4 standard deviations and is given for $m_{H^0} = 125.09$ GeV.

[4] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.5 for WH^0 production, 0.4 ± 0.4 for ZH^0 production, and 1.1 ± 1.0 for $t\overline{t}H^0$ production.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_{H^0} = 125.09$ GeV.

[6] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[7] AAD 21H present measurements of $H^0 \to b\overline{b}$ with a boosted vector boson ($p_T > 250$ GeV) using 139 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. Cross sections are given in their Table 6 and Fig. 4, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 5.

[8] AAD 21M search for VBF+γ, $H^0 \to b\overline{b}$ using 132 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV.

[9] SIRUNYAN 20BL search for boosted $H^0 \to b\overline{b}$ ($p_T(H^0) > 450$ GeV) using 137 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 2.5 standard deviations and is given for $m_{H^0} = 125$ GeV. A differential cross section as a function of Higgs boson p_T for ggF is shown in their Fig. 7, assuming the other production modes occur at the expected SM rates. The reported value is $3.7 \pm 1.2^{+0.8}_{-0.7}{}^{+0.8}_{-0.5}$ where the last uncertainty comes from theoretical modeling. We have combined the systematic uncertainties in quadrature.

[10] AABOUD 19U measure cross sections of $pp \to VH^0$, $H^0 \to b\overline{b}$ production as a function of the gauge boson transverse momentum using data of 79.8 fb^{-1}. The kinematic fiducial volumes used is based on the simplified template cross section framework (reduced stage-1). See their Table 3 and Fig. 3.

[11] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[12] AABOUD 18BN search for VH^0, $H^0 \to b\overline{b}$ ($V = W$, Z) using 79.8 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 4.9 standard deviations and is given for $m_{H^0} = 125$ GeV.

[13] AABOUD 18BN combine results of 79.8 fb^{-1} at $E_{cm} = 13$ TeV with results of VH^0 at $E_{cm} = 7$ and 8 TeV.

[14] AABOUD 18BN combine results of VH^0 at $E_{cm} = 7$, 8 and 13 TeV with results of VBF (+gluon fusion) and $t\overline{t}H^0$ at $E_{cm} = 7$, 8, and 13 TeV to perform a search for the $H^0 \to b\overline{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.4 standard deviations.

[15] AABOUD 18BQ search for $H^0 \to b\overline{b}$ produced through vector-boson fusion (VBF) and VBF+γ with 30.6 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[16] The signal strength is measured including all production modes (VBF, ggF, VH^0, $t\overline{t}H^0$).

[17] The signal strength is measured for VBF-only and others (ggF, VH^0, $t\overline{t}H^0$) are constrained to Standard Model expectations with uncertainties described in their Section VIII B.

[18] AALTONEN 18C use 5.4 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The upper limit at 95% CL on $p\overline{p} \to H^0 \to b\overline{b}$ is 33 times the SM predicion, which corresponds to a cross section of 40.6 pb.

[19] SIRUNYAN 18AE use 35.9 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to 3.3 standard deviations and is given for $m_{H^0} = 125.09$ GeV.

[20] SIRUNYAN 18AE combine the result of 35.9 fb^{-1} at $E_{cm} = 13$ TeV with the results obtained from data of up to 5.1 fb^{-1} at $E_{cm} = 7$ TeV and up to 18.9 fb^{-1} at $E_{cm} = 8$ TeV (CHATRCHYAN 14AI and KHACHATRYAN 15Z). The quoted signal strength corresponds to 3.8 standard deviations and is given for $m_{H^0} = 125.09$ GeV.

[21] SIRUNYAN 18DB combine the result of 77.2 fb^{-1} at $E_{cm} = 13$ TeV with the results obtained from data of up to 5.1 fb^{-1} at $E_{cm} = 7$ TeV and up to 18.9 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength corresponds to a significance of 4.8 standard deviations and is given for $m_{H^0} = 125.09$ GeV.

[22] SIRUNYAN 18DB combine results of 77.2 fb^{-1} at $E_{cm} = 13$ TeV with results of gluon fusion (ggF), VBF and $t\overline{t}H^0$ at $E_{cm} = 7$ TeV, 8 TeV and 13 TeV to perform a search for the $H^0 \to b\overline{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.6 standard deviations and is given for $m_{H^0} = 125.09$ GeV.

[23] SIRUNYAN 18E use 35.9 fb^{-1} at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV. They measure $\sigma \cdot B$ for gluon fusion production of $H^0 \to b\overline{b}$ with $p_T > 450$ GeV, $|\eta| < 2.5$ to be $74 \pm 48^{+17}_{-10}$ fb.

[24] AABOUD 17BA use 36.1 fb^{-1} at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV. They give $\sigma(\text{W H}) \cdot B(H^0 \to b\overline{b}) = 1.08^{+0.54}_{-0.47}$ pb and $\sigma(\text{Z H}) \cdot B(H^0 \to b\overline{b}) = 0.57^{+0.26}_{-0.23}$ pb.

[25] AABOUD 17BA combine 7, 8 and 13 TeV analyses. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[26] AABOUD 16X search for vector-boson fusion production of H^0 decaying to $b\overline{b}$ in 20.2 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[27] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.

[28] AAD 15G use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125.36$ GeV.

[29] KHACHATRYAN 15Z search for vector-boson fusion production of H^0 decaying to $b\overline{b}$ in up to 19.8 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[30] KHACHATRYAN 15Z combined vector boson fusion, WH^0, ZH^0 production, and $t\overline{t}H^0$ production results. The quoted signal strength is given for $m_{H^0} = 125$ GeV.

[31] CHATRCHYAN 14AI use up to 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 18.9 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_{H^0} = 125$ GeV. See also CHATRCHYAN 14AJ.

[32] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[33] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[34] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The quoted signal strengths are given in their Fig. 10 for m_{H^0} = 126 GeV. See also Fig. 13 of AAD 12DA.

[35] AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12O, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region m_{H^0} = 120–135 GeV, with a local significance of up to 3.3 σ. The local significance at m_{H^0} = 125 GeV is 2.8 σ, which corresponds to $(\sigma(H^0W) + \sigma(H^0Z)) \cdot B(H^0 \to b\overline{b}) = (0.23^{+0.09}_{-0.08})$ pb, compared to the Standard Model expectation at m_{H^0} = 125 GeV of 0.12 ± 0.01 pb. Superseded by AALTONEN 13M.

[36] CHATRCHYAN 12N obtain results based on 5.0 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.1 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_{H^0}=125.5 GeV. See also CHATRCHYAN 13Y.

[1] AAD 21 search for $H^0 \to \mu^+\mu^-$ using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 2.0 standard deviations and is given for m_{H^0} = 125.09 GeV. The upper limit on the cross section times branching fraction is 2.2 times the SM prediction at 95% CL, which corresponds to the branching fraction upper limit of 4.7×10^{-4} (assuming SM production cross sections).

[2] SIRUNYAN 21 search for $H^0 \to \mu^+\mu^-$ using 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 3.0 standard deviations and is given for m_{H^0} = 125.38 GeV.

[3] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[4] SIRUNYAN 19E search for $H^0 \to \mu^+\mu^-$ using 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV and combine with results of 7 TeV (5.0 fb^{-1}) and 8 TeV (19.7 fb^{-1}). The upper limit at 95% CL on the signal strength is 2.9, which corresponds to the SM Higgs boson branching fraction to a muon pair of 6.4×10^{-4}.

[5] AABOUD 17Y use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV, 20.3 fb^{-1} at 8 TeV and 4.5 fb^{-1} at 7 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[6] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_{H^0} = 125.09 GeV.

[7] KHACHATRYAN 15H use 5.0 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at 8 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[8] AAD 14AS search for $H^0 \to \mu^+\mu^-$ in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.5 GeV.

[1] AABOUD 19AQ use 36.1 fb^{-1} of data. The first, second and third quoted errors are statistical, experimental systematic and theory systematic uncertainties, respectively. The quoted signal strength is given for m_{H^0} = 125 GeV and corresponds to 4.4 standard deviations. Combining with 7 TeV and 8 TeV results (AAD 15AH), the observed significance is 6.4 standard deviations. The cross sections in the $H^0 \to \tau\tau$ decay channel (m_{H^0} = 125 GeV) are measured to $3.77^{+0.60}_{-0.59}$ (stat) $^{+0.87}_{-0.74}$ (syst) pb for the inclusive, $0.28 \pm 0.09^{+0.11}_{-0.09}$ pb for VBF, and $3.1 \pm 1.0^{+1.6}_{-1.3}$ pb for gluon-fusion production. See their Table XI for the cross sections in the framework of simplified template cross sections.

[2] SIRUNYAN 19AF use 35.9 fb^{-1} of data. H^0W/Z channels are added with a few updates on gluon fusion and vector boson fusion with respect to SIRUNYAN 18Y. The quoted signal strength is given for m_{H^0} = 125 GeV and corresponds to 5.5 standard deviations. The signal strengths for the individual production modes are: $1.12^{+0.53}_{-0.50}$ for gluon fusion, $1.13^{+0.45}_{-0.42}$ for vector boson fusion, $3.39^{+1.68}_{-1.54}$ for WH^0 and $1.23^{+1.62}_{-1.35}$ for ZH^0. See their Fig. 7 for other couplings (κ_V, κ_f).

[3] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.6 for gluon fusion, 1.3 ± 0.4 for vector boson fusion, -1.4 ± 1.4 for WH^0 production, $2.2^{+2.2}_{-1.8}$ for ZH^0 production, and $-1.9^{+3.7}_{-3.3}$ for $t\overline{t}H^0$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_{H^0} = 125.09 GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[6] SIRUNYAN 19AF use 35.9 fb^{-1} of data. The quoted signal strength is given for m_{H^0} = 125 GeV and corresponds to 2.3 standard deviations.

[7] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV. This combination is based on SIRUNYAN 18Y.

[8] SIRUNYAN 18Y use 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125.09 GeV and corresponds to 4.9 standard deviations.

[9] SIRUNYAN 18Y combine the result of 35.9 fb^{-1} at E_{cm} = 13 TeV with the results obtained from data of 4.9 fb^{-1} at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV (KHACHATRYAN 15AM). The quoted signal strength is given for m_{H^0} = 125.09 GeV and corresponds to 5.9 standard deviations.

[10] AAD 16AC measure the signal strength with $pp \to H^0W/ZX$ processes using 20.3 fb^{-1} of E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[11] AAD 16K use up to 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.36 GeV.

[12] AAD 15AH use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The third uncertainty in the measurement is theory systematics. The signal strength for the gluon fusion mode is $2.0 \pm 0.8^{+1.2}_{-0.8} \pm 0.3$ and that for vector boson fusion and W/ZH^0 production modes is $1.24^{+0.49}_{-0.45}{}^{+0.31}_{-0.29} \pm 0.08$. The quoted signal strength is given for m_{H^0} = 125.36 GeV.

[13] CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV. See also CHATRCHYAN 14AJ.

[14] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[15] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[16] AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The quoted signal strengths are given in their Fig. 10 for m_{H^0} = 126 GeV. See also Fig. 13 of AAD 12DA.

[17] CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.1 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_{H^0}=125.5 GeV. See also CHATRCHYAN 13Y .

$Z\gamma$ Final State

[1] AAD 20AG search for $H^0 \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The signal strength is $2.0 \pm 0.9^{+0.4}_{-0.3}$ at m_{H^0} = 125.09 GeV, which corresponds to a significance of 2.2 σ. The upper limit of $\sigma(pp \to H^0) \cdot B(H^0 \to Z\gamma)$ is 305 fb at 95% CL.

[2] SIRUNYAN 18DQ search for $H^0 \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted signal strength (see their Figs. 6 and 7) is given for m_{H^0} = 125 GeV.

[3] AABOUD 17AW search for $H^0 \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125.09 GeV. The upper limit on the branching ratio of $H^0 \to Z\gamma$ is 1.0% at 95% CL assuming the SM Higgs boson production.

[4] AAD 14J search for $H^0 \to Z\gamma \to \ell\ell\gamma$ in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.5 GeV.

[5] CHATRCHYAN 13BK search for $H^0 \to Z\gamma \to \ell\ell\gamma$ in 5.0 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.6 fb^{-1} at E_{cm} = 8 TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range m_{H^0} = 120–160 GeV at 95% CL. The quoted limit is given for m_{H^0} = 125 GeV, where 10 is expected for no signal.

$\gamma^*\gamma$ Final State

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
$1.5 \pm 0.5^{+0.2}_{-0.1}$		[1] AAD	21I	ATLS	pp, 13 TeV, $H^0 \to \ell\ell\gamma$, 139 fb^{-1}
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<4.0	95	[2] SIRUNYAN	18DQ	CMS	$pp \to H^0X$, 13 TeV, $H^0 \to \gamma^*\gamma$
<6.7	95	[3] KHACHATRY...16B		CMS	pp, 8 TeV, $ee\gamma$, $\mu\mu\gamma$

[1] AAD 21I search for $H^0 \to \ell\ell\gamma$ ($\ell = e,\ \mu$) in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The mass of dilepton $m_{\ell\ell}$ is smaller than 30 GeV. This region is dominated by the decay through γ^*. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for m_{H^0} = 125.09 GeV. The cross section times the branching ratio of $H^0 \to \ell\ell\gamma$ for $m_{\ell\ell} < 30$ GeV is measured to be $8.7 \pm 2.7^{+0.7}_{-0.6}$ fb.

[2] SIRUNYAN 18DQ search for $H^0 \to \gamma^*\gamma$, $\gamma^* \to \mu\mu$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The mass of γ^* is smaller than 50 GeV except in J/ψ and Υ mass regions. The quoted signal strength (see their Figs. 6 and 7) is given for m_{H^0} = 125 GeV.

[3] KHACHATRYAN 16B search for $H^0 \to \gamma^*\gamma \to e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ (with m(e^+e^-) < 3.5 GeV and m($\mu^+\mu^-$) < 20 GeV) in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for limits on individual channels.

Higgs Yukawa couplings

top Yukawa coupling

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
[−0.9, −0.7] or [0.7, 1.1]	95	[1] SIRUNYAN	21R	CMS	pp, 13 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<1.7	95	[2] SIRUNYAN	20C	CMS	pp, 13 TeV
<1.67	95	[3] SIRUNYAN	19BY	CMS	pp, 13 TeV
<2.1	95	[4] SIRUNYAN	18BU	CMS	pp, 13 TeV

[1] SIRUNYAN 21R constrain the ratio of the top quark Yukawa coupling y_t to its Standard Model value from $t\bar{t}H^0$ and tH^0 production rates using 137 fb^{-1} pp collision data at E_{cm} = 13 TeV. Assuming a SM Higgs couplings to τ's, the joint interval $-0.9 < \kappa_t (= y_t/y_t^{SM}) < -0.7$ and $0.7 < \kappa_t < 1.1$ is obtained at 95% CL (see their Fig. 17).

[2] SIRUNYAN 20C search for the production of four top quarks with same-sign and multilepton final states with 137 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its Standard Model value by comparing to the central value of a theoretical prediction (see their Refs. [1-2]), yielding $|y_t/y_t^{SM}| < 1.7$ at 95% CL. See their Fig. 5.

[3] SIRUNYAN 19BY measure the top quark Yukawa coupling from $t\bar{t}$ kinematic distributions, the invariant mass of the top quark pair and the rapidity difference between t and $\bar{t}$, in the ℓ+jets final state with 35.8 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling to its the Standard Model to be $1.07^{+0.34}_{-0.43}$ with an upper limit of 1.67 at 95% CL (see their Table III).

[4] SIRUNYAN 18BU search for the production of four top quarks with same-sign and multilepton final states with 35.9 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its the Standard Model by comparing to the central value of a theoretical prediction (see their Ref. [16]), yielding $|y_t/y_t^{SM}| < 2.1$ at 95% CL.

[1] SIRUNYAN 21R search for $t\bar{t}H^0$ in final states with electrons, muons and hadronically decaying τ leptons ($H^0 \to WW^*$, ZZ^*, $\tau\tau$) with 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 4.7 standard deviations and is given for m_{H^0} = 125 GeV.

[2] AABOUD 18AC combine results of $t\bar{t}H^0$, $H^0 \to \tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\bar{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\bar{q})$ with results of $t\bar{t}H^0$, $H^0 \to b\bar{b}$ (AABOUD 18T), $\gamma\gamma$ (AABOUD 18BO), $ZZ^*(\to 4\ell)$ (AABOUD 18AJ) in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV. See their Table 14.

[3] AAD 16AN: In the fit, relative branching ratios are fixed to those in the Standard Model. The quoted signal strength is given for m_{H^0} = 125.09 GeV.

[4] AAD 20Z measure $\sigma_{t\bar{t}H^0} \cdot B(H^0 \to \gamma\gamma)$ to be $1.64^{+0.38}_{-0.36}{}^{+0.17}_{-0.14}$ fb in 139 fb^{-1} of data at E_{cm} = 13 TeV.

[5] SIRUNYAN 20AS measure $\sigma_{t\bar{t}H^0} \cdot B(H^0 \to \gamma\gamma)$ to be $1.56^{+0.34}_{-0.32}$ fb in 137 fb^{-1} of data at E_{cm} = 13 TeV.

[6] SIRUNYAN 19R search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 35.9 fb^{-1} of data at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[7] AABOUD 18AC search for $t\bar{t}H^0$ production with H^0 decaying to $\tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\bar{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\bar{q})$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV. See their Table 13 and Fig. 13.

[8] AABOUD 18BK use 79.8 fb^{-1} data for $t\bar{t}H^0$ production with $H^0 \to \gamma\gamma$ and $ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) and 36.1 fb^{-1} for other decay channels at E_{cm} = 13 TeV. A significance of 5.8 standard deviations is observed for m_{H^0} = 125.09 GeV and its signal strength without the uncertainty of the $t\bar{t}H^0$ cross section is $1.32^{+0.28}_{-0.26}$. Combining with results of 7 and 8 TeV (AAD 16K), the significance is 6.3 standard deviations. Assuming Standard Model branching fractions, the total $t\bar{t}H^0$ production cross section at 13 TeV is measured to be $670 \pm 90^{+110}_{-100}$ fb.

[9] AABOUD 18T search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[10] SIRUNYAN 18BD search for $t\bar{t}H^0$, $H^0 \to b\bar{b}$ in the all-jet final state with 35.9 fb^{-1} pp collision data at E_{cm} = 13 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[11] SIRUNYAN 18BQ search for $t\bar{t}H^0$ in final states with electrons, muons and hadronically decaying τ leptons ($H^0 \to WW^*$, ZZ^*, $\tau\tau$) with 35.9 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for m_{H^0} = 125 GeV.

[12] SIRUNYAN 18L use up to 5.1, 19.7 and 35.9 fb^{-1} of pp collisions at E_{cm} = 7, 8, and 13 TeV, respectively. The quoted signal strength corresponds to a significance of 5.2 standard deviations and is given for m_{H^0} = 125.09 GeV. H^0 decay channels of WW^*, ZZ^*, $\gamma\gamma$, $\tau\tau$, and $b\bar{b}$ are used. See their Table 1 and Fig. 2 for results on individual channels.

[13] AAD 16AL search for $t\bar{t}H^0$ production with H^0 decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and $b\bar{b}$, $\tau\tau$, $\gamma\gamma$, WW^*, and ZZ^* in 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV. This paper combines the results of previous papers, and the new result of this paper only is: $\mu = 1.6 \pm 2.6$.

[14] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV.

[15] AAD 16K use up to 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The third uncertainty in the measurement is theory systematics. The quoted signal strength is given for m_{H^0} = 125.36 GeV.

[16] AAD 15 search for $t\bar{t}H^0$ production with H^0 decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted result on the signal strength is equivalent to an upper limit of 6.7 at 95% CL and is given for m_{H^0} = 125.4 GeV.

[17] AAD 15BC search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The corresponding upper limit is 3.4 at 95% CL. The quoted signal strength is given for m_{H^0} = 125 GeV.

[18] AAD 15T search for $t\bar{t}H^0$ production with H^0 resulting in multilepton final states (mainly from WW^*, $\tau\tau$, ZZ^*) in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The quoted result on the signal strength is given for m_{H^0} = 125 GeV and corresponds to an upper limit of 4.7 at 95% CL. The data sample is independent from AAD 15 and AAD 15BC.

[19] KHACHATRYAN 15AN search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The quoted result on the signal strength is equivalent to an upper limit of 4.2 at 95% CL and is given for m_{H^0} = 125 GeV.

[20] KHACHATRYAN 14H search for $t\bar{t}H^0$ production with H^0 decaying to $b\bar{b}$, $\tau\tau$, $\gamma\gamma$, WW^*, and ZZ^*, in 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_{H^0} = 125.6 GeV.

[21] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_{H^0} = 125 GeV.

[22] CHATRCHYAN 13X search for $t\overline{t}H^0$ production followed by $H^0 \to b\overline{b}$, one top decaying to $\ell\nu$ and the other to either $\ell\nu$ or $q\overline{q}$ in 5.0 fb^{-1} and 5.1 fb^{-1} of pp collisions at E_{cm} = 7 and 8 TeV. A limit on cross section times branching ratio which corresponds to (4.0–8.6) times the expected Standard Model cross section is given for m_{H^0} = 110–140 GeV at 95% CL. The quoted limit is given for m_{H^0} = 125 GeV, where 5.2 is expected for no signal.

H^0H^0 Production

The 95% CL limits are for the cross section (CS) and Higgs self coupling (κ_λ) scaling factors both relative to the SM predictions.

[1] SIRUNYAN 21K search for non-resonant H^0H^0 production using $H^0H^0 \to \gamma\gamma b\overline{b}$ with data of 137 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to \gamma\gamma b\overline{b}$ production cross section at 95% CL is measured to be 0.67 fb, which corresponds to about 7.7 times the SM prediction. The quartic coupling (VVH^0H^0, $V = W,Z$) scaling factor $\kappa_{2V}(= c_{2V})$ is measured to be $-1.3 < \kappa_{2V} < 3.5$ at 95% CL.

[2] AAD 20C combine results of up to 36.1 fb^{-1} data at E_{cm} = 13 TeV for $pp \to H^0H^0 \to b\overline{b}\gamma\gamma$, $b\overline{b}\tau\tau$, $b\overline{b}b\overline{b}$, $b\overline{b}WW^*$, $WW^*\gamma\gamma$, WW^*WW^* (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).

[3] AAD 20E search non-resonant for H^0H^0 production using $H^0H^0 \to b\overline{b}\ell\nu\ell\nu$, where one of the Higgs bosons decays to $b\overline{b}$ and the other decays to either WW^*, ZZ^*, or $\tau\tau$, with data of 139 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% CL is measured to be 1.2 pb, which corresponds to about 40 times the SM prediction.

[4] AAD 20X search for $H^0H^0 \to b\overline{b}b\overline{b}$ process via VBF with data of 126 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the SM non-resonant HH production cross section is 1460 fb at 95% CL, which corresponds to 840 times the SM prediction. The quartic coupling (VVH^0H^0, $V = W,Z$) scaling factor κ_{2V} is excluded in the region of $\kappa_{2V} < -0.43$ or $\kappa_{2V} > 2.56$ at 95% CL.

[5] AABOUD 19A search for H^0H^0 production using $H^0H^0 \to b\overline{b}b\overline{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\overline{b}b\overline{b}$ production cross section at 95% is measured to be 147 fb, which corresponds to about 12.9 times the SM prediction.

[6] AABOUD 19O search for H^0H^0 production using $H^0H^0 \to b\overline{b}WW^*$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% CL is calculated to be 10 pb from the observed upper limit on the $pp \to H^0H^0 \to b\overline{b}WW^*$ production cross section of 2.5 pb assuming the SM branching fractions. The former corresponds to about 300 times the SM prediction.

[7] AABOUD 19T search for H^0H^0 production using $H^0H^0 \to WW^*WW^*$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% is measured to be 5.3 pb, which corresponds to about 160 times the SM prediction.

[8] SIRUNYAN 19 search for H^0H^0 production using $H^0H^0 \to \gamma\gamma b\overline{b}$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to \gamma\gamma b\overline{b}$ production cross section at 95% CL is measured to be 2.0 fb, which corresponds to about 24 times the SM prediction. The effective Higgs boson self-coupling κ_λ ($= \lambda_{HHH} / \lambda^{SM}_{HHH}$) is constrainted to be $-11 < \kappa_\lambda < 17$ at 95% CL assuming all other Higgs boson couplings are at their SM value.

[9] SIRUNYAN 19AB search for H^0H^0 production using $H^0H^0 \to b\overline{b}b\overline{b}$, where 4 heavy flavor jets from two Higgs bosons are resolved, with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\overline{b}b\overline{b}$ production cross section at 95% is measured to be 847 fb, which corresponds to about 75 times the SM prediction.

[10] SIRUNYAN 19BE combine results of 13 TeV 35.9 fb^{-1} data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.

[11] SIRUNYAN 19H search for H^0H^0 production using $H^0H^0 \to b\overline{b}b\overline{b}$, where one of $b\overline{b}$ pairs is highly boosted and the other one is resolved, with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\overline{b}b\overline{b}$ production cross section at 95% is measured to be 1980 fb, which corresponds to about 179 times the SM prediction.

[12] AABOUD 18BU search for H^0H^0 production using $\gamma\gamma WW^*$ with the final state of $\gamma\gamma\ell\nu jj$ using data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% CL is measured to be 7.7 pb, which corresponds to about 230 times the SM prediction. The upper limit on the $pp \to H^0H^0 \to \gamma\gamma WW^*$ at 95% CL is measured to be 7.5 fb (see thier Table 6).

[13] AABOUD 18CQ search for H^0H^0 production using $H^0H^0 \to b\overline{b}\tau\tau$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\overline{b}\tau\tau$ production cross section at 95% is measured to be 30.9 fb, which corresponds to about 12.7 times the SM prediction.

[14] AABOUD 18CW search for H^0H^0 production using $H^0H^0 \to \gamma\gamma b\overline{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0$ production cross section at 95% is measured to be 0.73 pb, which corresponds to about 22 times the SM prediction. The effective Higgs boson self-coupling κ_λ is constrained to be $-8.2 < \kappa_\lambda < 13.2$ at 95% CL assuming all other Higgs boson couplings are at their SM value.

[15] SIRUNYAN 18A search for H^0H^0 production using $H^0H^0 \to b\overline{b}\tau\tau$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $gg \to H^0H^0 \to b\overline{b}\tau\tau$ production cross section is measured to be 75.4 fb, which corresponds to about 30 times the SM prediction. Limits on Higgs-boson trilinear coupling λ_{HHH} and top Yukawa coupling y_t are also given (see their Fig. 6).

[16] SIRUNYAN 18F search non-resonant for H^0H^0 production using $H^0H^0 \to b\overline{b}\ell\nu\ell\nu$, where $\ell\nu\ell\nu$ is either $WW \to \ell\nu\ell\nu$ or $ZZ \to \ell\ell\nu\nu$ (ℓ is e, μ or a leptonically decaying τ), with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $H^0H^0 \to b\overline{b}\ell\nu\ell\nu$ production cross section at 95% CL is measured to be 72 fb, which corresponds to about 79 times the SM prediction.

[17] SIRUNYAN 17CN search for H^0H^0 production using $H^0H^0 \to b\overline{b}\tau\tau$ with data of 18.3 fb^{-1} at E_{cm} = 8 TeV. Results are then combined with the published results of the $H^0H^0 \to \gamma\gamma b\overline{b}$ and $H^0H^0 \to b\overline{b}b\overline{b}$, which use data of up to 19.7 fb^{-1} at E_{cm} = 8 TeV. The upper limit on the $gg \to H^0H^0$ production cross section is measured to be 0.59 pb from $b\overline{b}\tau\tau$, which corresponds to about 59 times the SM prediction (gluon fusion). The combined upper limit is 0.43 pb, which is about 43 times the SM prediction. The quoted values are given for m_{H^0} = 125 GeV.

[18] AABOUD 16I search for H^0H^0 production using $H^0H^0 \to b\overline{b}b\overline{b}$ with data of 3.2 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to H^0H^0 \to b\overline{b}b\overline{b}$ production cross section is measured to be 1.22 pb. This result corresponds to about 108 times the SM prediction (gluon fusion), which is $11.3^{+0.9}_{-1.0}$ fb (NNLO+NNLL) including top quark mass effects. The quoted values are given for m_{H^0} = 125 GeV .

[19] KHACHATRYAN 16BQ search for H^0H^0 production using $H^0H^0 \to \gamma\gamma b\overline{b}$ with data of 19.7 fb^{-1} at E_{cm} = 8 TeV. The upper limit on the $gg \to H^0H^0 \to \gamma\gamma b\overline{b}$ production is measured to be 1.85 fb, which corresponds to about 74 times the SM prediction and is translated into 0.71 pb for $gg \to H^0H^0$ production cross section. Limits on Higgs-boson trilinear coupling λ are also given.

[20] AAD 15CE search for H^0H^0 production using $H^0H^0 \to b\overline{b}\tau\tau$ and $H^0H^0 \to \gamma\gamma WW$ with data of 20.3 fb^{-1} at E_{cm} = 8 TeV. These results are then combined with the published results of the $H^0H^0 \to \gamma\gamma b\overline{b}$ and $H^0H^0 \to b\overline{b}b\overline{b}$, which use data of up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The upper limits on the $gg \to H^0H^0$ production cross section are measured to be 1.6 pb, 11.4 pb, 2.2 pb and 0.62 pb from $b\overline{b}\tau\tau$, $\gamma\gamma WW$, $\gamma\gamma b\overline{b}$ and $b\overline{b}b\overline{b}$, respectively. The combined upper limit is 0.69 pb, which corresponds to about 70 times the SM prediction. The quoted results are given for m_{H^0} = 125.4 GeV. See their Table 4.

tH^0 production

VALUE	DOCUMENT ID		TECN	COMMENT

	[3] SIRUNYAN	19BK	CMS	pp, 13 TeV
	[4] KHACHATRY...16AU		CMS	pp, 8 TeV

[1] SIRUNYAN 21R search for tH^0 in final states with electrons, muons and hadronically decaying τ leptons ($H^0 \to WW^*$, ZZ^*, $\tau\tau$) with 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 1.4 standard deviations and is given for m_{H^0} = 125 GeV.

[2] AAD 20Z search for the tH^0 associated production using $H^0 \to \gamma\gamma$ in 139 fb^{-1} of data at E_{cm} = 13 TeV. An upper limit on its rate is set to be 12 times the Standard Model at 95% CL (m_{H^0} = 125.09 GeV).

[3] SIRUNYAN 19BK search for the tH^0 associated production using multilepton signatures ($H^0 \to WW^*$, $H^0 \to \tau\tau$, $H^0 \to ZZ^*$) and signatures with a single lepton and a $b\overline{b}$ pair ($H^0 \to b\overline{b}$) using 35.9 fb^{-1} at E_{cm} = 13 TeV. Results are combined with $H^0 \to \gamma\gamma$ (SIRUNYAN 18DS). The observed 95% CL upper limit on the tH^0 production cross section times $H^0 \to WW^* + \tau\tau + ZZ^* + b\overline{b} + \gamma\gamma$ branching fraction is 1.94 pb (assuming SM $t\overline{t}H^0$ production cross section). See their Table X and Fig. 14. The values outside the ranges of $[-0.9, -0.5]$ and $[1.0, 2.1]$ times the standard model top quark Yukawa coupling are excluded at 95% CL.

[4] KHACHATRYAN 16AU search for the tH^0 associated production in 19.7 fb^{-1} at E_{cm} = 8 TeV. The 95% CL upper limits on the tH^0 associated production cross section is measured to be 600–1000 fb depending on the assumed $\gamma\gamma$ branching ratios of the Higgs boson. The $\gamma\gamma$ branching ratio is varied to be by a factor of 0.5–3.0 of the Standard Model Higgs boson (m_{H^0} = 125 GeV). The results of the signal strengths for a negative Higgs-boson trilinear coupling are given. The results are given for m_{H^0} = 125 GeV.

H^0 Production Cross Section in pp Collisions at $\sqrt{s}$ = 13 TeV

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H_1^0 and H_2^0, where we define $m_{H_1^0} < m_{H_2^0}$], a pseudoscalar (A^0), and a charged Higgs pair ($H^\pm$). H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the Higgs sector which can be chosen to be m_{A^0} and $\tan\beta = v_2/v_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \leq m_Z$, $m_{H_2^0} \geq m_Z$, $m_{A^0} \geq m_{H_1^0}$, and $m_{H^\pm} \geq m_W$. However, as described in the review on "Status of Higgs Boson Physics" in this Volume these relations are violated by radiative corrections.

The observed signal at about 125 GeV, see section "H^0", can be interpreted as one of the neutral Higgs bosons of supersymmetric models. Unless otherwise noted, we identify the lighter scalar H_1^0 with the Higgs discovered at 125 GeV at the LHC (AAD 12AI, CHATRCHYAN 12N).

Unless otherwise noted, the experiments in e^+e^- collisions search for the processes $e^+e^- \to H_1^0 Z^0$ in the channels used for the Standard Model Higgs searches and $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays. Unless otherwise noted, the results are given in the m_h^{max} scenario, CARENA 13.

In $p\overline{p}$ and pp collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the A^0 mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H_1^0}$. As discussed in the review on "Status of Higgs Boson Physics" in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the t quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger t and $\tilde{t}$ masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections, and the results are given for the m_h^{mod+} benchmark scenario, see CARENA 13.

Mass Limits for heavy neutral Higgs bosons (H_2^0, A^0) in the MSSM

The limits rely on $pp \to H_2^0/A^0 \to \tau^+\tau^-$ and assume that H_2^0 and A^0 are (sufficiently) mass degenerate. The limits depend on $\tan\beta$.

[1] AABOUD 18G search for production of $H_2^0/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for excluded regions in the m_{A^0}– $\tan\beta$ plane in several MSSM scenarios.

[2] SIRUNYAN 18CX search for production of $H_{1,2}^0/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the m_{A^0}– $\tan(\beta)$ plane in several MSSM scenarios.

[3] AAD 20 combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 19 for excluded region in the hMSSM parameter space.

[4] AAD 20AA search for $H_2^0/A^0 \to \tau^+\tau^-$ produced by gluon fusion or b-associated production using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2(c) for excluded region in the M_h^{125} scenario of MSSM. Values of $\tan\beta > 8$ (21) are excluded for $m_{A^0} = 1.0$ (1.5) TeV at 95%CL.

[5] AAD 20C combine searches for a scalar resonance decaying to H^0H^0 in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 7(b) for the excluded region in the hMSSM parameter space.

[6] AAD 20L search for b-associated production of H_2^0 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in hMSSM, m_h^{mod+} and m_h^{mod-} scenarios of MSSM.

[7] SIRUNYAN 20AC search for gluon-fusion and b-associated production of A^0 decaying to ZH^0 in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for excluded regions in the $M_{h\text{EFT}}^{125}$ and hMSSM scenarios of the MSSM.

[8] SIRUNYAN 20AF search for $H_2^0/A^0 \to t\overline{t}$ with one or two charged leptons in the final state using kinematic variables in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for excluded region in the hMSSM scenario of MSSM. Values of $\tan\beta$ below 1.0–1.5 are excluded for $m_{A^0} = 0.4$–0.75 TeV at 95%CL.

[9] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 8 and 9 for excluded regions in various MSSM scenarios.

[10] SIRUNYAN 19CR search for production of H_2^0/A^0 in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for the excluded region in the MSSM parameter space in the m_h^{mod+} and hMSSM scenarios.

[11] SIRUNYAN 18A search for production of a scalar resonance decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 (lower) for excluded regions in the m_{A^0} – tanβ plane in the hMSSM scenario.

[12] SIRUNYAN 18BP search for production of $H_2^0/A^0 \to b\overline{b}$ by b-associated prodution in 35.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}$, m_{A^0} = 0.3–1.3 TeV, and Fig. 7 for excluded regions in the m_{A^0}– tan(β) plane in several MSSM scenarios.

[13] AABOUD 16AA search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $A^0 \to \tau^+\tau^-$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(a, b) for limits on cross section times branching ratio for m_{A^0} = 200–1200 GeV, and Fig. 5(c, d) for the excluded region in the MSSM parameter space in the m_h^{mod+} and hMSSM scenarios.

[14] KHACHATRYAN 16A search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $H_{1,2}^0/A^0 \to \mu^+\mu^-$ in 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.3 fb^{-1} at E_{cm} = 8 TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the m_h^{mod+} benchmark scenario and Fig. 9 for limits on cross section times branching ratio.

[15] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 12 for excluded region in the tanβ – cos($\beta-\alpha$) plane for $m_{H_2^0} = m_{A^0}$ = 300 GeV.

[16] KHACHATRYAN 15AY search for production of a Higgs boson in association with a b quark in the decay $H_{1,2}^0/A^0 \to b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for m_{A^0} = 100–900 GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.

[17] AAD 14AW search for production of a Higgs boson followed by the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ in 19.5–20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For m_{A^0} = 140 GeV, the region tan$\beta > 5.4$ is excluded at 95% CL in the m_h^{max} scenario.

[18] KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a b quark followed by the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ in 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For m_{A^0} = 140 GeV, the region tan$\beta > 3.8$ is excluded at 95% CL in the m_h^{max} scenario.

[19] AAD 13O search for production of a Higgs boson in the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ and $\mu^+\mu^-$ with 4.7–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For m_{A^0} = 110–170 GeV, tan$\beta \gtrsim 10$ is excluded, and for tanβ = 50, m_{A^0} below 470 GeV is excluded at 95% CL in the m_h^{max} scenario.

[20] AAIJ 13T search for production of a Higgs boson in the forward region in the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ in 1.0 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.

[21] CHATRCHYAN 13AG search for production of a Higgs boson in association with a b quark in the decay $H_{1,2}^0/A^0 \to b\overline{b}$ in 2.7–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For m_{A^0} = 90–350 GeV, upper bounds on tanβ of 18–42 at 95% CL are obtained in the m_h^{max} scenario with μ = +200 GeV.

[22] AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

[23] AALTONEN 12X search for associated production of a Higgs boson and a b quark in the decay $H_{1,2}^0/A^0 \to b\overline{b}$, with 2.6 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.

[24] ABAZOV 12G search for production of a Higgs boson in the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ with 7.3 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For m_{A^0} = 90–180 GeV, tan$\beta \gtrsim 30$ is excluded at 95% CL. in the m_h^{max} scenario.

[25] CHATRCHYAN 12K search for production of a Higgs boson in the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ with 4.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For m_{A^0} = 160 GeV, the region tan$\beta > 7.1$ is excluded at 95% CL in the m_h^{max} scenario. Superseded by KHACHATRYAN 14M.

[26] ABAZOV 11K search for associated production of a Higgs boson and a b quark, followed by the decay $H_{1,2}^0/A^0 \to b\overline{b}$, in 5.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for $\mu = -200$ GeV.

[27] ABAZOV 11W search for associated production of a Higgs boson and a b quark, followed by the decay $H_{1,2}^0/A^0 \to \tau\tau$, in 7.3 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.

[28] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on $\sigma \cdot$ B($H_{1,2}^0/A^0 \to \tau^+\tau^-$) for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[29] ABDALLAH 08B give limits in eight *CP*-conserving benchmark scenarios and some *CP*-violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.

[30] SCHAEL 06B make a combined analysis of the LEP data. The quoted limit is for the m_h^{max} scenario with m_t = 174.3 GeV. In the *CP*-violating CPX scenario no lower bound on $m_{H_1^0}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0) \cdot$ B($H^0 \to b\overline{b}, \tau^+\tau^-$) and $\sigma(H_1^0H_2^0) \cdot$ B(H_1^0,$H_2^0 \to b\overline{b}$,$\tau^+\tau^-$).

[31] ACOSTA 05Q search for $H_{1,2}^0/A^0$ production in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV with $H_{1,2}^0/A^0 \to \tau^+\tau^-$. At m_{A^0} = 100 GeV, the obtained cross section upper limit is above theoretical expectation.

[32] Search for $e^+e^- \to H_1^0A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to H_1^0Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for m_t=175 GeV, and for the m_h^{max} scenario.

[33] ABBIENDI 04M exclude $0.7 <$ tan$\beta < 1.9$, assuming m_t = 174.3 GeV. Limits for other MSSM benchmark scenarios, as well as for *CP* violating cases, are also given.

[34] ABBIENDI 03G search for $e^+e^- \to H_1^0Z$ followed by $H_1^0 \to A^0A^0$, $A^0 \to c\overline{c}$, gg, or $\tau^+\tau^-$. In the no-mixing scenario, the region $m_{H_1^0}$ = 45-85 GeV and m_{A^0} = 2-9.5 GeV is excluded at 95% CL.

[35] ACHARD 02H also search for the final state $H_1^0Z \to 2A^0q\overline{q}$, $A^0 \to q\overline{q}$. In addition, the MSSM parameter set in the "large-μ" and "no-mixing" scenarios are examined.

[36] AKEROYD 02 examine the possibility of a light A^0 with tanβ <1. Electroweak measurements are found to be inconsistent with such a scenario.

[37] HEISTER 02 excludes the range 0.7 <tanβ < 2.3. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on "Status of Higgs Boson Physics"). Concerning the mass limits for H^0 and A^0 listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about 125 GeV, see section "H^0", can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

Mass Limits in General two-Higgs-doublet Models

[1] AAD 21AF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell'^+\ell'^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 6 and 7 for excluded parameter regions of the 2HDM Type I and II.

[2] AAD 21AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^- b\overline{b}$ or $\ell^+\ell^- W^+W^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 14 for excluded regions in the parameter space of various 2HDMs.

[3] AAD 20 combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at E_{cm} = 13 TeV. See their Fig. 18 for excluded regions in various 2HDMs.

[4] AAD 20L search for b-associated production of H_2^0 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 11 for excluded regions in the flipped two Higgs doublet model.

[5] SIRUNYAN 20AA search for $H_2^0 \to ZA^0$, $A^0 \to b\overline{b}$ or $A^0 \to ZH_2^0$, $H_2^0 \to b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 8 and 9 for excluded regions in the parameter space of Type-II two Higgs doublet model.

[6] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for excluded regions in Type I and II two Higgs doublet models.

[7] SIRUNYAN 19AE search for a pseudoscalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for cross section limits for m_{A^0} = 25–70 GeV and comparison with some representative 2HDMs.

[8] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b associated production, decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$ (ℓ = e, μ) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 6 and 7 for excluded regions in the parameter space of various 2HDMs.

[9] AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^- b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for excluded regions in the parameter space of various 2HDMs.

[10] AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH^0 in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^- b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 7 and 8 for excluded regions in the parameter space in various 2HDMs.

[11] AABOUD 18BF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 8 and 9 for excluded parameter regions in 2HDM Type I and II.

[12] AABOUD 18CE search for the process $pp \to H_2^0/A^0\, t\overline{t}$ followed by the decay $H_2^0/A^0 \to t\overline{t}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio, and for lower limits on $\tan\beta$ for $m_{H_2^0}$, m_{A^0} = 0.4–1.0 TeV in the 2HDM type II.

[13] HALLER 18 perform global fits in the framework of two-Higgs-doublet models (type I, II, lepton specific, flipped). See their Fig. 8 for allowed parameter regions from fits to LHC H^0 measurements, Fig. 9 bottom and charm decays, Fig. 10 muon anomalous magnetic moment, Fig. 11 electroweak precision data, and Fig. 12 by combination of all data.

[14] SIRUNYAN 18BP search for production of $H_2^0/A^0 \to b\overline{b}$ by b-associated prodution in 35.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}$, m_{A^0} = 0.3–1.3 TeV, and Figs. 8 and 9 for excluded regions in the parameter space of type-II and flipped 2HDMs.

[15] SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH^0 in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^- b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for excluded regions in the parameter space in Type I and II 2HDMs.

[16] AABOUD 17AN search for production of a heavy H_2^0 and/or A^0 decaying to $t\overline{t}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 and Table III for excluded parameter regions in Type II Two-Higgs-Doublet-Models.

[17] SIRUNYAN 17AX search for $A^0 b\overline{b}$ production followed by the decay $A^0 \to \mu^+\mu^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Limits are set in the range m_{A^0} = 25–60 GeV. See their Fig. 5 for upper limits on $\sigma(A^0 b\overline{b})\cdot B(A^0 \to \mu^+\mu^-)$.

[18] AAD 16AX search for production of a heavy H^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^- q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 13 and 14 for excluded parameter regions in Type I and II models.

[19] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 11 for limits on $\tan\beta$ for m_{A^0} = 230–350 GeV.

[20] KHACHATRYAN 16W search for $A^0 b\overline{b}$ production followed by the decay $A^0 \to \tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 for upper limits on $\sigma(A^0 b\overline{b})\cdot B(A^0 \to \tau^+\tau^-)$.

[21] KHACHATRYAN 16Z search for $H_2^0 \to ZA^0$ followed by $A^0 \to b\overline{b}$ or $\tau^+\tau^-$, and $A^0 \to ZH_2^0$ followed by $H_2^0 \to b\overline{b}$ or $\tau^+\tau^-$, in 19.8 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 for cross section limits and Fig. 5 for excluded region in the parameter space.

[22] AAD 15BK search for production of a heavy H_2^0 decaying to H^0H^0 in the final state $b\overline{b}b\overline{b}$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 15–18 for excluded regions in the parameter space.

[23] AAD 15S search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.

[24] KHACHATRYAN 15BB search for H_2^0 , $A^0 \to \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.

[25] KHACHATRYAN 15N search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta-\alpha)$ plane for m_{A^0} = 300 GeV.

[26] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, H^0 decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H_2^0}$= 325–1025 GeV and m_{H^+}= 225–825 GeV.

[27] KHACHATRYAN 14Q search for $H_2^0 \to H^0H^0$ and $A^0 \to ZH^0$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for m_{H_2,A^0}= 260–360 GeV and their Figs. 7–9 for limits in two-Higgs-doublet models.

[28] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on $\sigma \cdot B(H_{1,2}^0/A^0 \to \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[29] ABBIENDI 05A search for $e^+e^- \to H_1^0 A^0$ in general Type-II two-doublet models, with decays H_1^0, $A^0 \to q\overline{q}$, gg, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[30] ABDALLAH 05D search for $e^+e^- \to H^0Z$ and H^0A^0 with H^0, A^0 decaying to two jets of any flavor including gg. The limit is for SM H^0Z production cross section with $B(H^0 \to jj) = 1$.

[31] ABDALLAH 04O search for $Z \to b\overline{b}H^0$, $b\overline{b}A^0$, $\tau^+\tau^-H^0$ and $\tau^+\tau^-A^0$ in the final states $4b$, $b\overline{b}\tau^+\tau^-$, and 4τ. See paper for limits on Yukawa couplings.

[32] ABDALLAH 04O search for $e^+e^- \to H^0Z$ and H^0A^0, with H^0, A^0 decaying to $b\overline{b}$, $\tau^+\tau^-$, or $H^0 \to A^0A^0$ at E_{cm} = 189–208 GeV. See paper for limits on couplings.

[33] ABBIENDI 02D search for $Z \to b\overline{b}H_1^0$ and $b\overline{b}A^0$ with $H_1^0/A^0 \to \tau^+\tau^-$, in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.

[34] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq$ 189 GeV. In addition to usual final states, the decays H_1^0, $A^0 \to q\overline{q}$, gg are searched for. See their Figs. 15,16 for excluded regions.

[35] ABBIENDI 99E search for $e^+e^- \to H^0A^0$ and H^0Z at E_{cm} = 183 GeV. The limit is with m_H=m_A in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the m_H-m_A plane. Updates the results of ACKERSTAFF 98S.

[36] See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta > 1$, the region $m_{H^0} + m_{A^0} \lesssim 87$ GeV, $m_{H^0} < 47$ GeV is excluded at 95% CL.

[37] PICH 92 analyse H^0 with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm$, η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

Mass Limits for H^0 with Vanishing Yukawa Couplings

These limits assume that H^0 couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

[1] AALTONEN 13K search for $H^0 \to WW^{(*)}$ in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A limit on cross section times branching ratio which corresponds to (1.3–6.6) times the expected cross section is given in the range m_{H^0} = 110–200 GeV at 95% CL.

[2] AALTONEN 13L combine all CDF searches with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[3] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[4] ABAZOV 13G search for $H^0 \to WW^{(*)}$ in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A limit on cross section times branching ratio which corresponds to (2–9) times the expected cross section is given for m_{H^0} = 100–200 GeV at 95% CL.

[5] ABAZOV 13H search for $H^0 \to \gamma\gamma$ in 9.6 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[6] ABAZOV 13I search for H^0 production in the final state with one lepton and two or more jets plus missing E_T in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The search is sensitive to WH^0, ZH^0 and vector-boson fusion Higgs production with $H^0 \to WW^{(*)}$. A limit on cross section times branching ratio which corresponds to (8–30) times the expected cross section is given in the range m_{H^0} = 100–200 GeV at 95% CL.

[7] ABAZOV 13J search for H^0 production in the final states $ee\mu$, $e\mu\mu$, $\mu\tau\tau$, and $e^\pm\mu^\pm$ in 8.6–9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The search is sensitive to WH^0, ZH^0 production with $H^0 \to WW^{(*)}$, $ZZ^{(*)}$, decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4–13.0) times the expected cross section is given in the range m_{H^0} = 100–200 GeV at 95% CL.

[8] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[9] CHATRCHYAN 13AL search for $H^0 \to \gamma\gamma$ in 5.1 fb^{-1} and 5.3 fb^{-1} of pp collisions at E_{cm} = 7 and 8 TeV.

[10] AAD 12N search for $H^0 \to \gamma\gamma$ with 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV in the mass range m_{H^0} = 110–150 GeV.

[11] AALTONEN 12AN search for $H^0 \to \gamma\gamma$ with 10 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 100–150 GeV.

[12] CHATRCHYAN 12AO use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, and CHATRCHYAN 12C.

[13] AALTONEN 09AB search for $H^0 \to \gamma\gamma$ in 3.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 70–150 GeV. Associated H^0W, H^0Z production and WW, ZZ fusion are considered.

[14] ABAZOV 08U search for $H^0 \to \gamma\gamma$ in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 70–150 GeV. Associated H^0W, H^0Z production and WW, ZZ fusion are considered. See their Tab. 1 for the limit on $\sigma \cdot B(H^0 \to \gamma\gamma)$, and see their Fig. 3 for the excluded region in the m_{H^0} — $B(H^0 \to \gamma\gamma)$ plane.

[15] SCHAEL 07 search for Higgs bosons in association with a fermion pair and decaying to WW^*. The limit is from this search and HEISTER 02L for a H^0 with SM production cross section.

[16] Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq$ 209 GeV. The limit is for a H^0 with SM production cross section.

[17] Updates ABREU 01F.

[18] ACHARD 03C search for $e^+e^- \to ZH^0$ followed by $H^0 \to WW^*$ or ZZ^* at E_{cm}= 200-209 GeV and combine with the ACHARD 02C result. The limit is for a H^0 with SM production cross section. For $B(H^0 \to WW^*) + B(H^0 \to ZZ^*) = 1$, $m_{H^0} > 108.1$ GeV is obtained. See fig. 6 for the limits under different BR assumptions.

[19] For $B(H^0 \to \gamma\gamma)$=1, m_{H^0} >117 GeV is obtained.

[20] ACHARD 02C search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq$ 209 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, m_{H^0} >114 GeV is obtained.

[21] AFFOLDER 01H search for associated production of a $\gamma\gamma$ resonance and a W or Z (tagged by two jets, an isolated lepton, or missing E_T). The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. See their Fig. 11 for limits with $B(H^0 \to \gamma\gamma) < 1$.

[22] ACCIARRI 00S search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at E_{cm}= 189 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, $m_{H^0} > 98$ GeV is obtained. See their Fig. 5 for limits on $B(H \to \gamma\gamma)\cdot\sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[23] BARATE 00L search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at E_{cm}= 88–202 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, $m_{H^0} > 109$ GeV is obtained. See their Fig. 3 for limits on $B(H \to \gamma\gamma)\cdot\sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[24] ABBIENDI 99O search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^0 with SM production cross section. See their Fig. 4 for limits on $\sigma(e^+e^- \to H^0Z^0)\times B(H^0 \to \gamma\gamma)\times B(X^0 \to f\overline{f})$ for various masses. Updates the results of ACKERSTAFF 98Y.

[25] ABBOTT 99B search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. Limits in the range of $\sigma(H^0 + Z/W)\cdot B(H^0 \to \gamma\gamma)$= 0.80–0.34 pb are obtained in the mass range m_{H^0}= 65–150 GeV.

[26] ABREU 99P search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$, and $e^+e^- \to H^0q\overline{q}$ with $H^0 \to \gamma\gamma$. See their Fig. 4 for limits on $\sigma\times B$. Explicit limits within an effective interaction framework are also given.

Mass Limits for H^0 Decaying to Invisible Final States

These limits are for a neutral scalar H^0 which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of H^0 to ordinary particles unless otherwise stated.

[1] AABOUD 19AI search for $H^0_{1,2}$ production by vector boson fusion and decay to invisible final states in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6(b) for limits on cross section times branching ratios for $m_{H^0_{1,2}}$ = 0.1–3 TeV.

[2] AAD 15BD search for $pp \to H^0WX$ and $pp \to H^0ZX$ with W or Z decaying hadronically and H^0 decaying to invisible final states in 20.3 fb^{-1} at E_{cm} = 8TeV. See their Fig. 6 for a limit on the cross section times branching ratio for m_{H^0} = 115–300 GeV.

[3] AAD 15BH search for events with a jet and missing E_T in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Limits on $\sigma(H'^0)$ $B(H'^0 \to$ invisible) < (44–10) pb (95%CL) is given for $m_{H'^0}$ = 115–300 GeV.

[4] AAD 14BA search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays to collimated pairs of e^+e^-, $\mu^+\mu^-$, or $\pi^+\pi^-$ plus invisible particles, in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 15 and 16 for limits on cross section times branching ratio.

[5] AAD 14O search for $pp \to H^0ZX$, $Z \to \ell\ell$, with H^0 decaying to invisible final states in 4.5 fb^{-1} at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. See their Fig. 3 for a limit on the cross section times branching ratio for m_{H^0} = 110–400 GeV.

[6] CHATRCHYAN 14B search for $pp \to H^0ZX$, $Z \to \ell\ell$ and $Z \to b\overline{b}$, and also $pp \to qqH^0X$ with H^0 decaying to invisible final states using data at E_{cm} = 7 and 8 TeV. See their Figs. 10, 11 for limits on the cross section times branching ratio for m_{H^0} = 100–400 GeV.

[7] AAD 13AG search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays to $\mu^+\mu^-X'^0$, in 1.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 7 for limits on cross section times branching ratio.

[8] AAD 13AT search for H^0 production in the decay $H^0 \to X^0X^0$, where X^0 eventually decays to clusters of collimated e^+e^- pairs, in 2.04 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 for limits on cross section times branching ratio.

[9] CHATRCHYAN 13BJ search for H^0 production in the decay chain $H^0 \to X^0X^0$, $X^0 \to \mu^+\mu^-X'^0$ in 5.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for limits on cross section times branching ratio.

[10] AAD 12AQ search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays mainly to $b\overline{b}$ in the muon detector, in 1.94 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 for limits on cross section times branching ratio for m_{H^0} = 120, 140 GeV, m_{X^0} = 20, 40 GeV in the $c\tau$ range of 0.5–35 m.

[11] AALTONEN 12AB search for H^0 production in the decay $H^0 \to X^0X^0$, where X^0 eventually decays to clusters of collimated $\ell^+\ell^-$ pairs, in 5.1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.

[12] AALTONEN 12U search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle with $c\tau \approx$ 1 cm which decays mainly to $b\overline{b}$, in 3.2 fb^{-1} of $p\overline{p}$

collisions at E_{cm} = 1.96 TeV. See their Figs. 9 and 10 for limits on cross section times branching ratio for m_{H^0} = (130–170) GeV, m_{X^0} = 20, 40 GeV.

[13] ABBIENDI 10 search for $e^+e^- \to H^0Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

[14] ABBIENDI 07 search for $e^+e^- \to H^0Z$ with $Z \to q\overline{q}$ and H^0 decaying to invisible final states. The H^0 width is varied between 1 GeV and 3 TeV. A limit $\sigma \cdot$B($H^0 \to$ invisible) < (0.07–0.57) pb (95%CL) is obtained at E_{cm} = 206 GeV for m_{H^0} = 60–114 GeV.

[15] Search for $e^+e^- \to H^0Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

[16] ACCIARRI 00M search for $e^+e^- \to ZH^0$ with H^0 decaying invisibly at E_{cm}=183–189 GeV. The limit assumes SM production cross section and B($H^0 \to$ invisible)=1. See their Fig. 6 for limits for smaller branching ratios.

Mass Limits for Light A^0

These limits are for a pseudoscalar A^0 in the mass range below $\mathcal{O}(10)$ GeV.

[1] AAD 20AE search for the decay $H^0 \to ZA^0$, $Z \to \ell^+\ell^-$, A^0 decaying hadronically ($A^0 \to gg$ or $s\overline{s}$), in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of production cross section and the $H^0 \to ZA^0$ branching ratio in the range 17–340 pb (95% CL) is given for m_{A^0} = 0.5–4.0 GeV, see their Table I.

[2] AABOUD 18AP search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10(b) for limits on B($H^0 \to A^0A^0$) in the range m_{A^0} = 1–2.5, 4.5–8 GeV, assuming a type-II two-doublet plus singlet model with tan(β) = 5.

[3] KHACHATRYAN 17AZ search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4, 5, and 6 for cross section limits in the range m_{A^0} = 5–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[4] ABLIKIM 16E search for the process $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$ and give limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 2.8×10^{-8}–5.0×10^{-6} (90% CL) for 0.212 $\leq m_{A^0} \leq$ 3.0 GeV. See their Fig. 5.

[5] KHACHATRYAN 16F search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 8 for cross section limits for m_{A^0} = 4–8 GeV.

[6] LEES 15H search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $c\overline{c}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to c\overline{c}$) in the range 7.4×10^{-5}–2.4×10^{-3} (90% CL) for 4.00 $\leq m_{A^0} \leq$ 8.95 and 9.10 $\leq m_{A^0} \leq$ 9.25 GeV. See their Fig. 6.

[7] LEES 13C search for the process $\Upsilon(2S,3S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\mu^+\mu^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–9.7)\times10^{-6}$ (90% CL) for 0.212 $\leq m_{A^0} \leq$ 9.20 GeV. See their Fig. 5(e) for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09Z.

[8] LEES 13L search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to gg or $s\overline{s}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to gg$) between 1×10^{-6} and 2×10^{-2} (90% CL) for 0.5 $\leq m_{A^0} \leq$ 9.0 GeV, and B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to s\overline{s}$) between 4×10^{-6} and 1×10^{-3} (90%CL) for 1.5 $\leq m_{A^0} \leq$ 9.0 GeV. See their Fig. 4.

[9] LEES 13R search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\tau^+\tau^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $0.9–13\times10^{-5}$ (90% CL) for 3.6 $\leq m_{A^0} \leq$ 9.2 GeV. See their Fig. 4 for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09P.

[10] ABLIKIM 12 searches for the process $\psi(3686) \to \pi\pi J/\psi$, $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$. It gives mass dependent limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 4×10^{-7}–2.1×10^{-5} (90% C.L.) for 0.212 $\leq m_{A^0} \leq$ 3.0 GeV. See their Fig. 2.

[11] CHATRCHYAN 12V search for A^0 production in the decay $A^0 \to \mu^+\mu^-$ with 1.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. A limit on $\sigma(A^0)$·B($A^0 \to \mu^+\mu^-$) in the range (1.5–7.5) pb is given for m_{A^0} = (5.5–8.7) and (11.5–14) GeV at 95% CL.

[12] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for 90 < m_{H^+} < 160 GeV.

[13] ABOUZAID 11A search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \mu^+\mu^-$) < 1.0×10^{-10} at 90% CL for m_{A^0} = 214.3 MeV.

[14] The search was motivated by PARK 05.

[15] DEL-AMO-SANCHEZ 11J search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to invisible final states. They give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to$ invisible) in the range $(1.9–4.5)\times10^{-6}$ (90% CL) for 0 $\leq m_{A^0} \leq$ 8.0 GeV, and $(2.7–37)\times10^{-6}$ for 8.0 $\leq m_{A^0} \leq$ 9.2 GeV.

[16] LEES 11H search for the process $\Upsilon(2S,3S) \to A^0\gamma$ with A^0 decaying hadronically and give limits on B($\Upsilon(2S,3S) \to A^0\gamma$)·B($A^0 \to$ hadrons) in the range 1×10^{-6}–8×10^{-5} (90% CL) for 0.3 < m_{A^0} < 7 GeV. The decay rates for $\Upsilon(2S)$ and $\Upsilon(3S)$ are assumed to be equal up to the phase space factor. See their Fig. 5.

[17] ANDREAS 10 analyze constraints from rare decays and other processes on a light A^0 with $m_{A^0} < 2m_\mu$ and give limits on its coupling to fermions at the level of 10^{-4} times the Standard Model value.

[18] HYUN 10 search for the decay chain $B^0 \to K^{*0}A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to K^{*0}A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(2.26–5.53)\times10^{-8}$ at 90%CL for m_{A^0} = 212–300 MeV. The limit for m_{A^0} = 214.3 MeV is 2.26×10^{-8}.

[19] HYUN 10 search for the decay chain $B^0 \to \rho^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to \rho^0A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(1.73–4.51)\times10^{-8}$ at 90%CL for m_{A^0} = 212–300 MeV. The limit for m_{A^0} = 214.3 MeV is 1.73×10^{-8}.

[20] AUBERT 09P search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \tau^+\tau^-$ for 4.03 < m_{A^0} < 9.52 and 9.61 < m_{A^0} < 10.10 GeV, and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $(1.5–16)\times10^{-5}$ (90% CL).

[21] AUBERT 09Z search for the process $\Upsilon(2S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for 0.212 < m_{A^0} < 9.3 GeV and give limits on B($\Upsilon(2S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–8)\times10^{-6}$ (90% CL).

[22] AUBERT 09Z search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for 0.212 < m_{A^0} < 9.3 GeV and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–5)\times10^{-6}$ (90% CL).

[23] TUNG 09 search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \gamma\gamma$ and give a limit on B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \gamma\gamma$) in the range $(2.4–10.7)\times10^{-7}$ at 90%CL for m_{A^0} = 194.3–219.3 MeV. The limit for m_{A^0} = 214.3 MeV is 2.4×10^{-7}.

[24] LOVE 08 search for the process $\Upsilon(1S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ (for $m_{A^0} < 2m_\tau$) and $A^0 \to \tau^+\tau^-$. Limits on B($\Upsilon(1S) \to A^0\gamma$) · B($A^0 \to \ell^+\ell^-$) in the range 10^{-6}–10^{-4} (90% CL) are given.

[25] BESSON 07 give a limit B($\Upsilon(1S) \to \eta_b\gamma$) · B($\eta_b \to \tau^+\tau^-$) < 0.27% (95% CL), which constrains a possible A^0 exchange contribution to the η_b decay.

[26] PARK 05 found three candidate events for $\Sigma^+ \to p\mu^+\mu^-$ in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with $m_{A^0} = 214.3 \pm 0.5$ MeV and the branching fraction B($\Sigma^+ \to pA^0$)·B($A^0 \to \mu^+\mu^-$) = $(3.1^{+2.4}_{-1.9}\pm1.5)\times10^{-8}$.

[27] BALEST 95 give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ 1.5×10^{-5} at 90% CL for m_{A^0} < 5 GeV. The limit becomes < 10^{-4} for m_{A^0} < 7.7 GeV.

[28] ANTREASYAN 90C give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ 5.6×10^{-5} at 90% CL for m_{A^0} < 7.2 GeV. A^0 is assumed not to decay in the detector.

Other Mass Limits

We use a symbol H^0_1 if mass < 125 GeV or H^0_2 if mass > 125 GeV. The notation H^0 is reserved for the 125 GeV particle.

[1] AAD 22A search for the decay chain $H^0 \to A^0 A^0 \to \mu^+\mu^- b\bar{b}$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for limits on the overall branching fraction in the range $m_{A^0} = 16$–62 GeV. See also Fig. 11 for limits without assuming A^0 is pseudoscalar.

[2] AAD 21AF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell'^+\ell'^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for upper limits on cross section times branching ratio for $m_{H_2^0} = 0.2$–2.0 TeV assuming ggF or VBF with narrow width approximation, and Fig. 5 for upper limits on cross section times branching ratio for $m_{H_2^0} = 0.4$–2.0 TeV assuming ggF, and with several assumptions on its width.

[3] AAD 21AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\bar{b}$, decaying to $ZH_2^0 \to \ell^+\ell^- b\bar{b}$ or $\ell^+\ell^- W^+W^-$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 9 and 13 for cross section limits for $m_{A^0} = 230$–800 GeV and $m_{H_2^0} = 130$–700 GeV.

[4] AAD 21AY search for production of a scalar resonance decaying to $\gamma\gamma$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(a) for limits on fiducial cross section times branching ratio for $m_{H_2^0} = 0.16$–3 TeV with narrow width approximation, and Table 2 with several assumptions on the width.

[5] AAD 21AZ search for production of A_2^0 decaying to $H^0 A_1^0$ followed by $H^0 \to \gamma\gamma$, $A_1^0 \to$ invisible in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 10–12 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar and a fermionic Dark Matter particle.

[6] AAD 21BB search for production of A_2^0 by gluon fusion or associated $A_2^0 b\bar{b}$ production, decaying to $H^0 A_1^0$ followed by $H^0 \to b\bar{b}$, $A_1^0 \to$ invisible in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[7] AAD 21BE search for production of A_1^0 associated with a single top quark and either a light quark or a W boson, decaying to invisible final states, in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 13–15 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar, which is assumed to decay to a pair of Dark Matter particles.

[8] ABRATENKO 21 search for a singlet scalar boson H_1^0 having a small mixing with the SM Higgs boson in the decay chain $K^+ \to H_1^0\pi^+$, $H_1^0 \to e^+e^-$ from data corresponding to 1.93×10^{20} protons on NuMI target. See their Fig. 2 for limits on the SM Higgs component of H_1^0 for $m_{H_1^0} = 3$–210 MeV.

[9] SIRUNYAN 21A search for $H_2^0 \to ZA^0$ with $Z \to \ell^+\ell^-$, A^0 decaying invisibly, in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for excluded regions in the mass parameter space of two Higgs doublet plus singlet model with a certain choice of the model parameters.

[10] TUMASYAN 21F search for gluon fusion production of H_3^0 decaying to $H^0 H_{1,2}^0 \to \tau^+\tau^- b\bar{b}$ in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 5 and 6 for limits on cross section times branching ratios for $m_{H_{1,2}^0} = 0.06$–2.8 TeV and $m_{H_3^0} = 0.24$–3.0 TeV.

[11] AAD 20AA search for $H_2^0/A^0 \to \tau^+\tau^-$ produced by gluon fusion or b-associated production using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2(a), 2(b) for limits on the product of cross section and branching ratio for $m_{H_2^0}$, $m_{A^0} = 0.2$–2.5 TeV.

[12] AAD 20AI search for ZH^0 production followed by the decay $H^0 \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The search looks for collimated $A^0 \to b\overline{b}$ decays and is complementary to AABOUD 18BX. See their Fig. 10 for limits on the product of production cross section and branching ratios in the range m_{A^0} = 15–30 GeV.

[13] AAD 20AO search for gluon fusion production of H_2^0 decaying to $H^0H^0 \to \tau^+\tau^- b\overline{b}$ (with hadronically decaying $\tau^+\tau^-$) using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of production cross section times branching ratios in the range 28–817 fb (95% CL) is given for m_{A^0} = 1.0–3.0 TeV, see their Fig. 13.

[14] AAD 20C combine searches for a scalar resonance decaying to H^0H^0 in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 5(a) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.26–3 TeV.

[15] AAD 20L search for b-associated production of H_2^0 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits on the product of cross section and branching ratio for $m_{H_2^0}$ = 0.45–1.4 TeV.

[16] AAD 20X search for vector-boson-fusion production of H_2^0 decaying to H^0H^0 using 126 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on the product of cross section and branching ratio for the assumptions of a narrow- and broad-width resonance.

[17] AAIJ 20AL search for dimuon resonance in the mass range 0.2–60 GeV in 5.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV, in inclusive and b quark associated production. Displaced decays are searched for for masses below 3 GeV. See their Figs. 7–9 for cross section limits and Fig. 10 for limits for mixing angle in two Higgs doublet plus singlet model (at 90% CL).

[18] SIRUNYAN 20 search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ or $\tau^+\tau^-\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range m_{A^0} = 4–15 GeV.

[19] SIRUNYAN 20AA search for $H_2^0 \to ZA^0$, $A^0 \to b\overline{b}$ or $A^0 \to ZH_2^0$, $H_2^0 \to b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of cross section and branching ratio for $m_{H_2^0}$ = 0.12–1 TeV and m_{A^0} = 0.03–1 TeV.

[20] SIRUNYAN 20AC search for gluon-fusion production of A^0 decaying to ZH^0 in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on the product of cross section and branching ratios for m_{A^0} = 220–400 GeV.

[21] SIRUNYAN 20AD search for lepton-flavor violating decays $H_2^0 \to \mu\tau$, $e\tau$ of gluon-fusion-produced H_2^0 in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 (9) and Table 5 (6) for limits on production cross section times branching ratio for $m_{H_2^0}$ = 0.2–0.9 TeV for the $\mu\tau$ ($e\tau$) final state.

[22] SIRUNYAN 20AF search for $H_2^0/A^0 \to t\overline{t}$ with one or two charged leptons in the final state using kinematic variables in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 5 and 6 for limits on top Yukawa coupling of H_2^0 and A^0 for $m_{H_2^0}$, m_{A^0} = 0.4–0.75 TeV for various width assumptions.

[23] SIRUNYAN 20AP search for the decay H^0 or $H_2^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ (for $m_{H_2^0}$ = 300 GeV) with boosted final-state topology in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range m_{A^0} = 3.6–21 GeV, and Figs. 8 and 9 for its interpretation in terms of models with two Higgs doublets plus a singlet.

[24] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on the product of cross section and branching ratio for $m_{H_2^0}$ = 0.2–3 TeV.

[25] SIRUNYAN 20Z search for $H_{1,2}^0$ or A^0 production in association with a $t\overline{t}$ pair, decaying to e^+e^- or $\mu^+\mu^-$, in 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on production cross section times branching ratio for $m_{H_{1,2}^0}$, m_{A^0} = 15–75 GeV and 108–340 GeV.

[26] AABOUD 19A search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 27.5–36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9(a) for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.26–3 TeV.

[27] AABOUD 19AG search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-b\overline{b}$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 (a) for limits on the product of production cross section (normalized to the SM) and branching ratios in the range m_{A^0} = 20–60 GeV.

[28] AABOUD 19O search for a scalar resonance decaying to $H^0H^0 \to b\overline{b}WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 (left) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–3 TeV.

[29] AABOUD 19T search for a scalar resonance decaying to $H^0H^0 \to WW^*WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_2^0}$ = 260–500 GeV, assuming SM decay rates for the H^0.

[30] AABOUD 19V combine published ATLAS data to constrain two-Higgs-doublet plus singlet pseudoscalar model with A_1^0 decaying to invisible final states. See their Fig. 19 for excluded parameter regions.

[31] AABOUD 19Y search for a narrow scalar resonance produced by gluon fusion or b associated production, decaying to $\mu^+\mu^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 4 and 5(a) for cross section limits for $m_{H_2^0}$ = 0.2–1.0 TeV.

[32] AALTONEN 19 search for b associated production of a scalar particle decaying to $b\overline{b}$ in 5.4 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 100–300 GeV.

[33] SIRUNYAN 19 search for a narrow scalar resonance decaying to $H^0H^0 \to \gamma\gamma b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 (left) for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–900 GeV.

[34] SIRUNYAN 19AE search for a scalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for cross section limits for m_{A^0} = 25–70 GeV.

[35] SIRUNYAN 19AN search for production of A_2^0 decaying to $H^0A_1^0$ followed by $H^0 \to b\overline{b}$, $A_1^0 \to$ invisible in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, in the mass range $m_{A_2^0}$ = 0.2–1.6 TeV, $m_{A_1^0}$ = 0.15–0.5 TeV. See their Fig. 6 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[36] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b-associated production, decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$ ($\ell = e, \mu$) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for cross section limits for m_{A^0} = 0.22–1.0 TeV.

[37] SIRUNYAN 19B search for gluon fusion production of narrow scalar resonance with large transverse momentum, decaying to $b\overline{b}$, in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 7 and 8 for limits on cross section times branching ratio for the resonance mass of 50–350 GeV.

[38] SIRUNYAN 19BB search for the decay $H_1^0 \to \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 35.9 fb^{-1} at E_{cm} = 13 TeV. See their Figs. 4–6 for limits on cross section times branching ratio for $m_{H_1^0}$ = 80–110 GeV (some results in Fig. 5 for $m_{H_1^0}$ = 70–110 GeV).

[39] SIRUNYAN 19BD search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on the product of cross section times branching ratios in the range m_{A^0} = 20–62.5 GeV. See also their Figs. 6 and 7 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[40] SIRUNYAN 19BE combine searches for $H_2^0 \to H^0H^0$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV in various H^0 decay modes, from SIRUNYAN 18A, SIRUNYAN 18AF, SIRUNYAN 18CW, SIRUNYAN 19, and SIRUNYAN 19H. See their Fig. 3 for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.25–3 TeV.

[41] SIRUNYAN 19BQ search for production of $H_{1,2}^0$ decaying to $A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 90–150 GeV, m_{A^0} = 0.25–3.55 GeV.

[42] SIRUNYAN 19CR search for production of H_2^0/A^0 in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on cross section times branching ratio.

[43] SIRUNYAN 19H search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where one $b\overline{b}$ pair is resolved and the other not. Limits on cross section times branching ratios for $m_{H_2^0}$ = 0.75–1.6 TeV are obtained and combined with data from SIRUNYAN 18AF. See their Fig. 5 (right).

[44] AABOUD 18AA search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying hadronically, in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8(a) for limits on cross section times branching ratio for $m_{H_2^0}$ = 1.0–6.8 TeV.

[45] AABOUD 18AG search for the decay $H^0 \to A^0A^0 \to \gamma\gamma gg$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 and Table 6 for cross section limits in the range m_{A^0} = 20–60 GeV.

[46] AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^-b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for cross section limits for m_{A^0} = 230–800 GeV and $m_{H_2^0}$ = 130–700 GeV.

[47] AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH^0 in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for cross section limits for m_{A^0} = 0.2–2 TeV. See also AABOUD 18CC.

[48] AABOUD 18BF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–1.2 TeV assuming ggF or VBF with the NWA. See their Fig. 7 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.4–1.0 TeV assuming ggF, and with several assumptions on its width.

[49] AABOUD 18BU search for a narrow scalar resonance decaying to $H^0H^0 \to \gamma\gamma WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–500 GeV.

[50] AABOUD 18BX search for associated production of WH^0 or ZH^0 followed by the decay $H^0 \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on cross section times branching ratios for m_{A^0} = 20–60 GeV. See also their Fig. 10 for the dependence of the limit on A^0 lifetime.

[51] AABOUD 18CQ search for a narrow scalar resonance decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 (above) for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1000 GeV.

[52] AABOUD 18F search for production of a narrow scalar resonance decaying to W^+W^- and ZZ, followed by hadronic decays of W and Z, in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(c) for limits on cross section times branching ratio for $m_{H_2^0}$ = 1.2–3.0 TeV.

[53] AAIJ 18AM search for gluon-fusion production of $H_{1,2}^0$ decaying to $\mu\tau$ in 2 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 45–195 GeV.

[54] AAIJ 18AQ search for gluon-fusion production of a scalar particle A^0 decaying to $\mu^+\mu^-$ in 1.99 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 0.98 fb^{-1} at E_{cm} = 7 TeV. See

their Fig. 4 for limits on cross section times branching ratio for $m_{A^0} = 5.5$–15 GeV (using the $E_{cm} = 8$ TeV data set).

[55] AAIJ 18AQ search for the decay $H^0 \to A^0 A^0$, with one of the A^0 decaying to $\mu^+\mu^-$, in 1.99 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and 0.98 fb^{-1} at $E_{cm} = 7$ TeV. See their Fig. 5 (right) for limits on the product of branching ratios for $m_{A^0} = 5.5$–15 GeV (using the $E_{cm} = 8$ TeV data set).

[56] SIRUNYAN 18AF search for a narrow scalar resonance decaying to $H^0 H^0 \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, where both $b\overline{b}$ pairs are not resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0} = 0.75$–3 TeV.

[57] SIRUNYAN 18BA search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^- q\overline{q}$, and $\ell^+\ell^-\nu\overline{\nu}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 10 and 11 for upper limits on cross section times branching ratio for $m_{H_2^0} = 0.13$–3 TeV with several assumptions on its width and on the fraction of Vector-Boson-Fusion of the total production cross section.

[58] SIRUNYAN 18CW search for a narrow scalar resonance decaying to $H^0 H^0 \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, where both $b\overline{b}$ pairs are resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0} = 260$–1200 GeV.

[59] SIRUNYAN 18DK search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying to $\ell^+\ell^-$ or hadronically, in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0} = 0.35$–4 TeV for different assumptions on the width of the resonance.

[60] SIRUNYAN 18DT search for the decay $H^0 \to A^0 A^0 \to \tau^+\tau^- b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on the product of branching ratios in the range $m_{A^0} = 15$–60 GeV. See also their Fig. 8 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[61] SIRUNYAN 18DU search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 35.9 fb^{-1} (taken in 2016) of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 (right) for limits on cross section times branching ratio for $m_{H_2^0} = 0.5$–5 TeV for several values of its width-to-mass ratio.

[62] SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH^0 in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^- b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for cross section limits for $m_{A^0} = 0.8$–2 TeV.

[63] SIRUNYAN 18EE search for the decay $H^0 \to A^0 A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for limits on the product of branching ratios in the range $m_{A^0} = 15$–62.5 GeV, normalized to the SM production cross section. See also their Fig. 5 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[64] SIRUNYAN 18F search for a narrow scalar resonance decaying to $H^0 H^0 \to WWb\overline{b}$ or $ZZb\overline{b}$ in the final state $\ell\ell\nu\nu b\overline{b}$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratios for $m_{H_2^0} = 250$–900 GeV.

[65] AABOUD 17 search for production of a scalar resonance decaying to $Z\gamma$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for the limits on cross section times branching ratio for $m_{H_2^0} = 0.25$–3.0 TeV.

[66] AABOUD 17AP search for production of a scalar resonance decaying to $\gamma\gamma$ in 36.7 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4(a) for limits on fiducial cross section times branching ratio for $m_{H_2^0} = 0.2$–2.7 TeV with narrow width approximation.

[67] AABOUD 17AW search for production of a scalar resonance decaying to $Z\gamma$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0} = 0.25$–2.4 TeV.

[68] KHACHATRYAN 17AZ search for the decay $H^0 \to A^0 A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^- b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Figs. 4, 5, and 6 for cross section limits in the range $m_{A^0} = 5$–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[69] KHACHATRYAN 17D search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and 2.7 fb^{-1} at $E_{cm} = 13$ TeV. See their Figs. 3 and 4 for the limits on cross section times branching ratio for $m_{H_2^0} = 0.2$–2.0 TeV.

[70] KHACHATRYAN 17R search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 12.9 fb^{-1} (taken in 2016) of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_2^0} = 0.5$–4.5 TeV for several values of its width-to-mass ratio. Limits from combination with KHACHATRYAN 16M are shown in their Figs. 4 and 6.

[71] SIRUNYAN 17CN search for a narrow scalar resonance decaying to $H^0 H^0 \to b\overline{b}\tau^+\tau^-$ in 18.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 5 (above) and Table II for limits on the cross section times branching ratios for $m_{H_2^0} = 0.3$–1 TeV, and Fig. 6 (above) and Table III for the corresponding limits by combining with data from KHACHATRYAN 16BQ and KHACHATRYAN 15R.

[72] SIRUNYAN 17Y search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and 2.7 fb^{-1} at $E_{cm} = 13$ TeV. See their Figs. 3, 4 and Table 3 for limits on cross section times branching ratio for $m_{H_2^0} = 0.7$–3.0 TeV, and Fig. 5 for the corresponding limits for $m_{H_2^0} = 0.2$–3.0 TeV from combination with KHACHATRYAN 17D data.

[73] AABOUD 16AB search for associated production of WH^0 with the decay $H^0 \to A^0 A^0 \to b\overline{b}b\overline{b}$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratios for $m_{A^0} = 20$–60 GeV.

[74] AABOUD 16AE search for production of a narrow scalar resonance decaying to W^+W^- and ZZ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H_2^0} = 0.5$–3 TeV.

[75] AABOUD 16H search for production of a scalar resonance decaying to $\gamma\gamma$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 12 for limits on cross section times branching ratio for $m_{H_2^0} = 0.2$–2 TeV with different assumptions on the width.

[76] AABOUD 16I search for a narrow scalar resonance decaying to $H^0 H^0 \to b\overline{b}b\overline{b}$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10(c) for limits on cross section times branching ratios for $m_{H_2^0} = 0.5$–3 TeV.

[77] AAD 16AX search for production of a heavy H^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^- q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig.12 for upper limits on $\sigma(H^0)$ B($H^0 \to ZZ$) for m_{H^0} ranging from 140 GeV to 1000 GeV.

[78] AAD 16C search for production of a heavy H^0 state decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Figs. 12, 13, and 16 for upper limits on $\sigma(H^0)$ B($H^0 \to W^+W^-$) for m_{H^0} ranging from 300 GeV to 1000 or 1500 GeV with various assumptions on the total width of H^0.

[79] AAD 16L search for the decay $H^0 \to A^0 A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 4 (upper right) for limits on cross section times branching ratios (normalized to the SM H^0 cross section) for $m_{A^0} = 10$–60 GeV.

[80] AAD 16L search for the decay $H_2^0 \to A^0 A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 4 (lower right) for limits on cross section times branching ratios for $m_{H_2^0} = 600$ GeV and $m_{A^0} = 10$–245 GeV, and Table 5 for limits for $m_{H_2^0}$= 300 and 900 GeV.

[81] AALTONEN 16C search for electroweak associated production of $H_1^0 H^\pm$ followed by the decays $H^\pm \to H_1^0 W^*$, $H_1^0 \to \gamma\gamma$ for $m_{H_1^0} = 10$–105 GeV and $m_{H^\pm} = 30$–300 GeV. See their Fig. 3 for excluded parameter region in a two-doublet model in which H_1^0 has no direct decay to fermions.

[82] KHACHATRYAN 16BG search for a narrow scalar resonance decaying to $H^0 H^0 \to b\overline{b}b\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on the cross section times branching ratios for $m_{H_2^0} = 1.15$–3 TeV.

[83] KHACHATRYAN 16BQ search for a resonance decaying to $H^0 H^0 \to \gamma\gamma b\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 9 for limits on the cross section times branching ratios for $m_{H_2^0} = 0.26$–1.1 TeV.

[84] KHACHATRYAN 16F search for the decay $H^0 \to H_1^0 H_1^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 8 for cross section limits for $m_{H_1^0}$ = 4–8 GeV.

[85] KHACHATRYAN 16M search for production of a narrow resonance decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and 3.3 fb^{-1} at $E_{cm} = 13$ TeV. See their Fig. 3 (top) for limits on cross section times branching ratio for $m_{H_2^0} = 0.5$–4 TeV.

[86] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $H^0 H^0 \to b\overline{b}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 8 (lower right) for cross section limits for $m_{H_2^0} = 260$–350 GeV.

[87] KHACHATRYAN 16P search for gluon fusion production of an A^0 decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 10 for cross section limits for $m_{H_2^0} = 220$–350 GeV.

[88] AAD 15BK search for production of a heavy H_2^0 decaying to $H^0 H^0$ in the final state $b\overline{b}b\overline{b}$ in 19.5 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 14(c) for $\sigma(H_2^0)$ B($H_2^0 \to H^0 H^0$) for $m_{H_2^0} = 500$–1500 GeV with $\Gamma_{H_2^0} = 1$ GeV.

[89] AAD 15BZ search for the decay $H^0 \to A^0 A^0 \to \mu^+\mu^-\tau^+\tau^-$ ($m_{H^0} = 125$ GeV) in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{A^0} = 3.7$–50 GeV.

[90] AAD 15BZ search for a state H_2^0 via the decay $H_2^0 \to A^0 A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{H_2^0} = 100$–500 GeV and $m_{A^0} = 5$ GeV.

[91] AAD 15CE search for production of a heavy H_2^0 decaying to $H^0 H^0$ in the final states $b\overline{b}\tau^+\tau^-$ and $\gamma\gamma WW^*$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and combine with data from AAD 15H and AAD 15BK. A limit $\sigma(H_2^0)$ B($H_2^0 \to H^0 H^0$) $<$ 2.1–0.011 pb (95% CL) is given for $m_{H_2^0} = 260$–1000 GeV. See their Fig. 6.

[92] AAD 15H search for production of a heavy H_2^0 decaying to $H^0 H^0$ in the finalstate $\gamma\gamma b\overline{b}$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV.A limit of $\sigma(H_2^0)$ B($H_2^0 \to H^0 H^0$) $<$ 3.5–0.7 pb is given for $m_{H_2^0} = 260$–500 GeV at 95% CL. See their Fig. 3.

[93] AAD 15S search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 3 for cross section limits for $m_{A^0} = 200$–1000 GeV.

[94] KHACHATRYAN 15AW search for production of a heavy state H_2^0 of an electroweak singlet extension of the Standard Model via the decays of H_2^0 to W^+W^- and ZZ in up to 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 19.7 fb^{-1} at $E_{cm} = 8$ TeV in the range $m_{H_2^0} = 145$–1000 GeV. See their Figs. 8 and 9 for limits in the parameter space of the model.

[95] KHACHATRYAN 15BB search for production of a resonance H^0 decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^0} = 150$–850 GeV.

[96] KHACHATRYAN 15N search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^- b\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 3 for limits on cross section times branching ratios for $m_{A^0} = 225$–600 GeV.

[97] KHACHATRYAN 15O search for production of a high-mass narrow resonance A^0 decaying to $ZH^0 \to q\overline{q}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on cross section times branching ratios for $m_{A^0} = 800$–2500 GeV.

[98] KHACHATRYAN 15R search for a narrow scalar resonance decaying to $H^0 H^0 \to b\overline{b}b\overline{b}$ in 17.9 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 5 (top) for limits on cross section times branching ratios for $m_{H_2^0} = 0.27$–1.1 TeV.

[99] AAD 14AP search for a second H^0 state decaying to $\gamma\gamma$ in addition to the state at about 125 GeV in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 for limits on cross section times branching ratio for m_{H^0} = 65–600 GeV.

[100] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, H^0 decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and m_{H^+}= 225–925 GeV.

[101] CHATRCHYAN 14G search for a second H^0 state decaying to $WW^{(*)}$ in addition to the observed signal at about 125 GeV using 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.4 fb^{-1} at E_{cm} = 8 TeV. See their Fig. 21 (right) for cross section limits in the mass range 110–600 GeV.

[102] KHACHATRYAN 14P search for a second H^0 state decaying to $\gamma\gamma$ in addition to the observed signal at about 125 GeV using 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. See their Figs. 27 and 28 for cross section limits in the mass range 110–150 GeV.

[103] AALTONEN 13P search for production of a heavy Higgs boson H'^0 that decays into a charged Higgs boson $H^\pm$ and a lighter Higgs boson H^0 via the decay chain $H'^0 \to H^\pm W^\mp$, $H^\pm \to W^\pm H^0$, $H^0 \to b\overline{b}$ in the final state $\ell\nu$ plus 4 jets in 8.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 4 for limits on cross section times branching ratio in the $m_{H^\pm}$–m_{H^0} plane for m_{H^0} = 126 GeV.

[104] CHATRCHYAN 13BJ search for H^0 production in the decay chain $H^0 \to A^0A^0$, $A^0 \to \mu^+\mu^-$ in 5.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for limits on cross section times branching ratio.

[105] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[106] ABBIENDI 10 search for $e^+e^- \to ZH^0$ with the decay chain $H^0 \to \tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0 + (\gamma \text{ or } Z^*)$, when $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$ are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on m_{H^0} of 108.4 (107.0) GeV (95% CL) is obtained for SM ZH^0 cross section and B($H^0 \to \tilde{\chi}_1^0\tilde{\chi}_2^0$) = 1.

[107] SCHAEL 10 search for the process $e^+e^- \to H^0Z$ followed by the decay chain $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ with $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$ at E_{cm} = 183–209 GeV. For a H^0ZZ coupling equal to the SM value, B($H^0 \to A^0A^0$) = B($A^0 \to \tau^+\tau^-$) = 1, and m_{A^0} = 4–10 GeV, m_{H^0} up to 107 GeV is excluded at 95% CL.

[108] ABAZOV 09V search for H^0 production followed by the decay chain $H^0 \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ or $\mu^+\mu^-\tau^+\tau^-$ in 4.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 3 for limits on $\sigma(H^0)$·B($H^0 \to A^0A^0$) for m_{A^0} = 3.6–19 GeV.

[109] ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with decays H_1^0, $A^0 \to q\overline{q}$, gg, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[110] ABBIENDI 04K search for $e^+e^- \to H^0Z$ with H^0 decaying to two jets of any flavor including gg. The limit is for SM production cross section with B($H^0 \to jj$) = 1.

[111] ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to W or Z bosons, assuming SM decays of the Higgs. Results in Fig. 26.

[112] ACHARD 04B search for $e^+e^- \to H^0Z$ with H^0 decaying to $b\overline{b}$, $c\overline{c}$, or gg. The limit is for SM production cross section with B($H^0 \to jj$) = 1.

[113] ACHARD 04F search for H^0 with anomalous coupling to gauge boson pairs in the processes $e^+e^- \to H^0\gamma$, $e^+e^-H^0$, H^0Z with decays $H^0 \to f\overline{f}$, $\gamma\gamma$, $Z\gamma$, and W^*W at E_{cm} = 189–209 GeV. See paper for limits.

[114] ABBIENDI 03F search for $H^0 \to$ anything in $e^+e^- \to H^0Z$, using the recoil mass spectrum of $Z \to e^+e^-$ or $\mu^+\mu^-$. In addition, it searched for $Z \to \nu\overline{\nu}$ and $H^0 \to e^+e^-$ or photons. Scenarios with large width or continuum H^0 mass distribution are considered. See their Figs. 11–14 for the results.

[115] ABBIENDI 03G search for $e^+e^- \to H_1^0Z$ followed by $H_1^0 \to A^0A^0$, $A^0 \to c\overline{c}$, gg, or $\tau^+\tau^-$ in the region $m_{H_1^0}$ = 45-86 GeV and m_{A^0} = 2-11 GeV. See their Fig. 7 for the limits.

[116] Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq 209$ GeV. The limit is for a H^0 with SM production cross section and B($H^0 \to f\overline{f}$)=0 for all fermions f.

[117] For B($H^0 \to \gamma\gamma$)=1, $m_{H^0} > 113.1$ GeV is obtained.

[118] HEISTER 02M search for $e^+e^- \to H^0Z$, assuming that H^0 decays to $q\overline{q}$, gg, or $\tau^+\tau^-$ only. The limit assumes SM production cross section.

[119] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq 189$ GeV. In addition to usual final states, the decays H_1^0, $A^0 \to q\overline{q}$, gg are searched for. See their Figs. 15,16 for excluded regions.

[120] ACCIARRI 00R search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$, $Z\gamma$, or $\gamma\gamma$. See their Fig. 3 for limits on σ·B. Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.

[121] ACCIARRI 00R search for the two-photon type processes $e^+e^- \to e^+e^-H^0$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$. See their Fig. 4 for limits on $\Gamma(H^0 \to \gamma\gamma)$·B($H^0 \to \gamma\gamma$or $b\overline{b}$) for m_{H^0}=70–170 GeV.

[122] GONZALEZ-GARCIA 98B use DØ limit for $\gamma\gamma$ events with missing E_T in $p\overline{p}$ collisions (ABBOTT 98) to constrain possible ZH or WH production followed by unconventional $H \to \gamma\gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.

[123] KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no H_1^0ZZ coupling and obtain $m_{H_1^0} \gtrsim$ 5 GeV or $m_{A^0} \gtrsim$ 5 GeV for $\tan\beta > 50$. Other Higgs bosons are assumed to be much heavier.

[124] ALEXANDER 96H give B($Z \to H^0\gamma$)×B($H^0 \to q\overline{q}$) < 1–4 × 10^{-5} (95%CL) and B($Z \to H^0\gamma$)×B($H^0 \to b\overline{b}$) < 0.7–2 × 10^{-5} (95%CL) in the range 20 < m_{H^0} <80 GeV.

SEARCHES FOR A HIGGS BOSON WITH STANDARD MODEL COUPLINGS

These listings are based on experimental searches for a scalar boson whose couplings to W, Z and fermions are precisely those of the Higgs boson predicted by the three-generation Standard Model with the minimal Higgs sector.

For a review and a bibliography, see the review on "Status of Higgs Boson Physics."

Indirect Mass Limits for H^0 from Electroweak Analysis

The mass limits shown below apply to a Higgs boson H^0 with Standard Model couplings whose mass is a priori unknown.

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

VALUE (GeV)		DOCUMENT ID		TECN
$\mathbf{90^{+21}_{-18}}$	[1]	HALLER	18	RVUE
• • • We do not use the following data for averages, fits, limits, etc. • • •				
91^{+30}_{-23}	[2]	BAAK	12	RVUE
94^{+25}_{-22}	[3]	BAAK	12A	RVUE
91^{+31}_{-24}	[4]	ERLER	10A	RVUE
129^{+74}_{-49}	[5]	LEP-SLC	06	RVUE

[1] HALLER 18 make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2018. The direct mass measurement at the LHC is not used in the fit.

[2] BAAK 12 make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is 120^{+12}_{-5} GeV.

[3] BAAK 12A make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.

[4] ERLER 10A makes Standard Model fits to Z and neutral current parameters, m_t, m_W measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.

[5] LEP-SLC 06 make Standard Model fits to Z parameters from LEP/SLC and m_t, m_W, and Γ_W measurements available in 2005 with $\Delta\alpha_{had}^{(5)}(m_Z) = 0.02758 \pm 0.00035$. The 95% CL limit is 285 GeV.

Charged Higgs Bosons ($H^{\pm}$ and $H^{\pm\pm}$), Searches for

CONTENTS:

$H^{\pm}$ (charged Higgs) mass limits for $m_{H^+} < m(top)$

Unless otherwise stated, LEP limits assume $B(H^+ \to \tau^+\nu)+B(H^+ \to c\overline{s})=1$, and hold for all values of $B(H^+ \to \tau^+\nu_\tau)$, and assume H^+ weak isospin of $T_3=+1/2$. In the following, $\tan\beta$ is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

Limits obtained at the LHC are given in the m_h^{mod-} benchmark scenario, see CARENA 13, and hold for all $\tan\beta$ values.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current

measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in e^+e^- collisions at and above the Z pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^+} \lesssim 45$ GeV, and are meanwhile superseded by the searches in higher energy e^+e^- collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^- \to H^+H^-$ process. Limits from $b \to s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

[1] AAD 15AF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.5 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. Upper limits on B($t \to bH^+$) B($H^+ \to \tau\nu$) between 2.3×10^{-3} and 1.3×10^{-2} (95% CL) are given for $m_{H^+} = 80$–160 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 140$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.

[2] KHACHATRYAN 15AX search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. Upper limits on B($t \to bH^+$) B($H^+ \to \tau\nu$) between 1.2×10^{-2} and 1.5×10^{-3} (95% CL) are given for $m_{H^+} = 80$–160 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 155$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.

[3] LEP 13 give a limit that refers to the Type II scenario. The limit for B($H^+ \to \tau\nu$) = 1 is 94 GeV (95% CL), and for B($H^+ \to cs$) = 1 the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode $H^+ \to A^0W^*$ with $A^0 \to b\overline{b}$, which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if $m_{A^0} > 12$ GeV.

[4] ABBIENDI 12 also search for the decay mode $H^+ \to A^0W^*$ with $A^0 \to b\overline{b}$.

[5] AAD 21V search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H^+} = 0.2$–2 TeV. See also their Fig. 7 for the excluded region in the parameter space of the hMSSM and the following MSSM benchmark scenarios: M_h^{125}, $M_h^{125}(\widetilde{\chi})$, $M_h^{125}(\widetilde{\tau})$, M_h^{125}(alignment), $M_{h_1}^{125}$(CPV).

[6] SIRUNYAN 21W search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 137 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratio for $m_{H^+} = 0.2$–3.0 TeV, and also for limits on the fraction of the triplet vev contribution to the W mass in the Georgi-Machacek model.

[7] AAD 20W search for dijet resonances in events with isolated leptons using 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. As a byproduct, $H^+ \to t\overline{b}$ produced in association with $\overline{t}b$ is searched for. Limits on the product of cross section times branching ratio for $m_{H^+} = 0.6$–2 TeV are given in their Fig. 5(c).

[8] SIRUNYAN 20AO search for $H^+ \to t\overline{b}$ produced in association with $t(b)$ in all jet final states in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 6 for limits on the product of cross section times branching ratio for $m_{H^+} = 0.2$–3 TeV. Limits for s-channel production are also given for $m_{H^+} = 0.8$–3 TeV. See also Fig. 7 for the corresponding limits in scenarios in the minimal supersymmetric standard model. Cross section limits from combined results with SIRUNYAN 20AV are given in Fig. 8.

[9] SIRUNYAN 20AV search for $H^+ \to t\overline{b}$ produced in association with $t(b)$ in final states with one or two leptons, in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 5 for limits on the product of cross section times branching ratio for $m_{H^+} = 0.2$–3 TeV, and their Fig. 6 for the corresponding limits in scenarios in the minimal supersymmetric standard model.

[10] SIRUNYAN 20BE search for $t \to bH^+$ followed by the decay $H^+ \to c\overline{s}$ in pair produced top quark events using 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. Limits on the branching ratio in the range 1.68–0.25% (95%CL) are given for $m_{H^+} = 80$–160 GeV, see their Fig. 4.

[11] SIRUNYAN 19AH search for H^+ in the decay of a pair-produced t quark, or in associated tbH^+ or nonresonant $b\overline{b}H^+W^-$ production, followed by $H^+ \to \tau^+\nu$, in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. Upper limits on cross section times branching ratio between 6 pb and 5 fb (95% CL) are given for $m_{H^+} = 80$–3000 GeV (including the non-resonant production near the top quark mass), see their Fig. 6 (left). See their Fig. 6 (right) for the excluded regions in the $m_h^{\rm mod-}$ scenario of the MSSM.

[12] SIRUNYAN 19BP search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^+} = 0.3$–2.0 TeV, and also for limits on the fraction of the triplet vev contribution to the W mass in the Georgi-Machacek model.

[13] SIRUNYAN 19CC search for $t \to bH^+$ from pair produced top quarks, with the decay chain $H^+ \to W^+A^0$, $A^0 \to \mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 2 for limits on the product of branching ratios for $m_{A^0} = 15$–75 GeV.

[14] SIRUNYAN 19CQ search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu q\overline{q}$ or $q\overline{q}\ell^+\ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^+} = 0.6$–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[15] AABOUD 18BW search for $\overline{t}bH^+$ associated production or the decay $t \to bH^+$, followed by $H^+ \to \tau^+\nu$, in 36.1 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 8(a) for upper limits on cross section times branching ratio for $m_{H^+} = 90$–2000 GeV, and Fig. 8(b) for limits on B($t \to bH^+$) B($H^+ \to \tau^+\nu$) for $m_{H^+} = 90$–160 GeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

[16] AABOUD 18CD search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 36.1 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 8 for upper limits on cross section times branching ratio for $m_{H^+} = 0.2$–2 TeV. See also their Fig. 9 for the excluded region in the parameter space of the $m_h^{\rm mod-}$ and hMSSM scenarios of the MSSM. The theory predictions overlaid to the experimental limits to determine the excluded m_{H^+} range are shown without their respective uncertainty band.

[17] AABOUD 18CH search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 36.1 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^\pm} = 0.2$–0.9 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[18] HALLER 18 give 95% CL lower limits on m_{H^+} of 590 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for B($b \to s\gamma$).

[19] SIRUNYAN 18DO search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. See their Fig. 3 for upper limits on B($t \to bH^+$) for $m_{H^+} = 90$–150 GeV assuming that B($H^+ \to c\overline{b}$) = 1 and B($t \to bH^+$) + B($t \to bW^+$) = 1.

[20] MISIAK 17 give 95% CL lower limits on m_{H^+} between 570 and 800 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for $B(b \to s(d)\gamma)$.

[21] SIRUNYAN 17AE search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 15.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^\pm}$ = 0.2–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[22] AABOUD 16A search for $t(b)\,H^\pm$ associated production followed by $H^+ \to \tau^+\nu$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Upper limits on $\sigma(t(b)\,H^\pm)\,B(H^+ \to \tau\nu)$ between 1.9 pb and 15 fb (95% CL) are given for m_{H^+} = 200–2000 GeV, see their Fig. 6. See their Fig. 7 for the excluded regions in the hMSSM scenario.

[23] AAD 16AJ search for $t(b)\,H^\pm$ associated production followed by $H^\pm \to tb$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for upper limits on $\sigma(t(b)\,H^\pm)\,B(H^+ \to tb)$ for m_{H^+} = 200–600 GeV.

[24] AAD 16AJ search for $H^\pm$ production from quark-antiquark annihilation, followed by $H^\pm \to tb$, in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 10 for upper limits on $\sigma(H^\pm)\,B(H^+ \to tb)$ for m_{H^+} = 400–3000 GeV.

[25] AAD 15AF search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Upper limits on $\sigma(tH^\pm)\,B(H^+ \to \tau\nu)$ between 760 and 4.5 fb (95% CL) are given for m_{H^+} = 180–1000 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.

[26] AAD 15M search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to q\overline{q}\ell^+\ell^-$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^\pm}$ = 200–1000 GeV, and Fig. 3 for limits on thetriplet vacuum expectation value fraction in the Georgi-Machacek model.

[27] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to tb$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Upper limits on $\sigma(tH^\pm)\,B(H^+ \to t\overline{b})$ between 2.0 and 0.13 pb (95% CL) are given for m_{H^+} = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[28] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Upper limits on $\sigma(tH^\pm)\,B(H^+ \to \tau\nu)$ between 380 and 25 fb (95% CL) are given for m_{H^+} = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[29] KHACHATRYAN 15BF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Upper limits on $B(t \to bH^+)\,B(H^+ \to c\overline{s})$ between 1.2×10^{-2} and 6.5×10^{-2} (95% CL) are given for m_{H^+} = 90–160 GeV.

[30] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, H^0 decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and m_{H^+}= 225–925 GeV.

[31] AALTONEN 14A measure $B(t \to b\tau\nu) = 0.096 \pm 0.028$ using 9 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. For m_{H^+}= 80–140 GeV, this measured value is translated to a limit $B(t \to bH^+) < 0.059$ at 95% CL assuming $B(H^+ \to \tau^+\nu) = 1$.

[32] AAD 13AC search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ (flavor unidentified) in 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on $B(t \to bH^+)$ between 0.05 and 0.01 (95%CL) are given for m_{H^+}=90–150 GeV and $B(H^+ \to c\overline{s})$=1.

[33] AAD 13V search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ through violation of lepton universality with 4.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on $B(t \to bH^+)$ between 0.032 and 0.044 (95% CL) are given for m_{H^+} = 90–140 GeV and $B(H^+ \to \tau^+\nu) = 1$. By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for m_{H^+} = 90–160 GeV. See their Fig. 7 for the excluded region in the m_h^{max} scenario of the MSSM.

[34] AAD 12BH search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 4.6 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 7 TeV. Upper limits on $B(t \to bH^+)$ between 0.01 and 0.05 (95% CL) are given for m_{H^+} = 90–160 GeV and $B(H^+ \to \tau^+\nu) = 1$. See their Fig. 8 for the excluded region in the m_h^{max} scenario of the MSSM.

[35] CHATRCHYAN 12AA search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 2 fb^{-1} of pp collisions at E_{cm} = 7 TeV. Upper limits on $B(t \to bH^+)$ between 0.019 and 0.041 (95% CL) are given for m_{H^+} = 80–160 GeV and $B(H^+ \to \tau^+\nu)$=1.

[36] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on $B(t \to bH^+)$ for $90 < m_{H^+} < 160$ GeV.

[37] DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b \to s\gamma$, B, B_s mixings, and $Z \to b\overline{b}$. The limit holds irrespective of $\tan\beta$.

[38] AALTONEN 09AJ search for $t \to bH^+$, $H^+ \to c\overline{s}$ in $t\overline{t}$ events in 2.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Upper limits on $B(t \to bH^+)$ between 0.08 and 0.32 (95% CL) are given for m_{H^+} = 60–150 GeV and $B(H^+ \to c\overline{s}) = 1$.

[39] ABAZOV 09AC search for $t \to bH^+$, $H^+ \to \tau^+\nu$ in $t\overline{t}$ events in 0.9 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Upper limits on $B(t \to bH^+)$ between 0.19 and 0.25 (95% CL) are given for m_{H^+} = 80–155 GeV and $B(H^+ \to \tau^+\nu) = 1$. See their Fig. 4 for an excluded region in a MSSM scenario.

[40] ABAZOV 09AG measure $t\overline{t}$ cross sections in final states with ℓ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ in 1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV, which constrains possible $t \to bH^+$ branching fractions. Upper limits (95% CL) on $B(t \to bH^+)$ between 0.15 and 0.40 (0.48 and 0.57) are given for $B(H^+ \to \tau^+\nu) = 1$ ($B(H^+ \to c\overline{s}) = 1$) for m_{H^+} = 80–155 GeV.

[41] ABAZOV 09AI search for $t \to bH^+$ in $t\overline{t}$ events in 1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Final states with ℓ + jets ($\ell = e, \mu$), $\ell\ell$, and $\tau\ell$ are examined. Upper limits on $B(t \to bH^+)$ (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for $B(H^+ \to \tau^+\nu) = 1$ ($B(H^+ \to c\overline{s}) = 1$) for m_{H^+} = 80–155 GeV. For $B(H^+ \to \tau^+\nu) = 1$ also a simultaneous extraction of $B(t \to bH^+)$ and the $t\overline{t}$ cross section is performed, yielding a limit on $B(t \to bH^+)$ between 0.12 and 0.26 for m_{H^+} = 80–155 GeV. See their Figs. 5–8 for excluded regions in several MSSM scenarios.

[42] ABAZOV 09P search for H^+ production by $q\overline{q}'$ annihilation followed by $H^+ \to t\overline{b}$ decay in 0.9 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Cross section limits in several two-doublet models are given for m_{H^+} = 180–300 GeV. A region with $20 \lesssim \tan\beta \lesssim 70$ is excluded (95% CL) for 180 GeV $\lesssim m_{H^+} \lesssim$ 184 GeV in type-I models.

[43] ABULENCIA 06E search for associated H^0W production in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A fit is made for $t\overline{t}$ production processes in dilepton, lepton + jets, and lepton + τ final states, with the decays $t \to W^+b$ and $t \to H^+b$ followed by $H^+ \to \tau^+\nu$, $c\overline{s}$, $t^*\overline{b}$, or W^+H^0. Within the MSSM the search is sensitive to the region $\tan\beta < 1$ or > 30 in the mass range m_{H^+} = 80–160 GeV. See Fig. 2 for the excluded region in a certain MSSM scenario.

[44] ABDALLAH 04I search for $e^+e^- \to H^+H^-$ with $H^\pm$ decaying to $\tau\nu$, cs, or W^*A^0 in Type-I two-Higgs-doublet models.

[45] ABBIENDI 03 give a limit $m_{H^+} > 1.28\tan\beta$ GeV (95%CL) in Type II two-doublet models.

[46] ABAZOV 02B search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ at E_{cm}=1.8 TeV. For m_{H^+}=75 GeV, the region $\tan\beta > 32.0$ is excluded at 95%CL. The excluded mass region extends to over 140 GeV for $\tan\beta$ values above 100.

[47] BORZUMATI 02 point out that the decay modes such as $b\overline{b}\,W$, $A^0\,W$, and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.

[48] ABBIENDI 01Q give a limit $\tan\beta/m_{H^+} < 0.53$ GeV^{-1} (95%CL) in Type II two-doublet models.

[49] BARATE 01E give a limit $\tan\beta/m_{H^+} < 0.40$ GeV^{-1} (90% CL) in Type II two-doublet models. An independent measurement of $B \to \tau\nu_\tau X$ gives $\tan\beta/m_{H^+} < 0.49$ GeV^{-1} (90% CL).

[50] GAMBINO 01 use the world average data in the summer of 2001 $B(b \to s\gamma) = (3.23 \pm 0.42) \times 10^{-4}$. The limit applies for Type-II two-doublet models.

[51] AFFOLDER 00I search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ in $p\overline{p}$ collisions at E_{cm}=1.8 TeV. The excluded mass region extends to over 120 GeV for $\tan\beta$ values above 100 and $B(\tau\nu) = 1$. If $B(t \to bH^+) \gtrsim 0.6$, m_{H^+} up to 160 GeV is excluded. Updates ABE 97L.

[52] ABBOTT 99E search for a charged Higgs boson in top decays in $p\overline{p}$ collisions at E_{cm}=1.8 TeV, by comparing the observed $t\overline{t}$ cross section (extracted from the data assuming the dominant decay $t \to bW^+$) with theoretical expectation. The search is sensitive to regions of the domains $\tan\beta \lesssim 1$, $50 < m_{H^+}$(GeV) $\lesssim 120$ and $\tan\beta \gtrsim 40$, $50 < m_{H^+}$(GeV) $\lesssim 160$. See Fig. 3 for the details of the excluded region.

[53] ACKERSTAFF 99D measure the Michel parameters ρ, ξ, η, and $\xi\delta$ in leptonic τ decays from $Z \to \tau\tau$. Assuming e-μ universality, the limit $m_{H^+} > 0.97\tan\beta$ GeV (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.

[54] ACCIARRI 97F give a limit $m_{H^+} > 2.6\tan\beta$ GeV (90% CL) from their limit on the exclusive $B \to \tau\nu_\tau$ branching ratio.

[55] AMMAR 97B measure the Michel parameter ρ from $\tau \to e\nu\nu$ decays and assumes e/μ universality to extract the Michel η parameter from $\tau \to \mu\nu\nu$ decays. The measurement is translated to a lower limit on m_{H^+} in a two-doublet model $m_{H^+} > 0.97\tan\beta$ GeV (90% CL).

[56] COARASA 97 reanalyzed the constraint on the ($m_{H^\pm}$,$\tan\beta$) plane derived from the inclusive $B \to \tau\nu_\tau X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.

[57] GUCHAIT 97 studies the constraints on m_{H^+} set by Tevatron data on $\ell\tau$ final states in $t\overline{t} \to (Wb)(Hb)$, $W \to \ell\nu$, $H \to \tau\nu_\tau$. See Fig. 2 for the excluded region.

[58] MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_c \to \tau\nu_\tau$ background to $B_u \to \tau\nu_\tau$ decays. Stronger limits are obtained.

[59] STAHL 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit $m_{H^+} > 1.5\tan\beta$ GeV (90% CL) for a two-doublet model. See also STAHL 94.

[60] ALAM 95 measure the inclusive $b \to s\gamma$ branching ratio at $\Upsilon(4S)$ and give $B(b \to s\gamma) < 4.2\times10^{-4}$ (95% CL), which translates to the limit $m_{H^+} > [244 + 63/(\tan\beta)^{1.3}]$ GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.

[61] BUSKULIC 95 give a limit $m_{H^+} > 1.9\tan\beta$ GeV (90% CL) for Type-II models from $b \to \tau\nu_\tau X$ branching ratio, as proposed in GROSSMAN 94.

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} > m(top)$

Limits obtained at the LHC are given in the m_h^{mod-} benchmark scenario, see CARENA 13, and depend on the $\tan\beta$ values.

[1] AABOUD 18BW search for $\overline{t}bH^+$ associated production in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

$H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin T_3 is thus restricted to two possibilities depending on lepton chiralities: $T_3(H^{\pm\pm}) = \pm1$, with the coupling $g_{\ell\ell}$ to $\ell_L^-\ell_L'^-$ and $\ell_R^+\ell_R'^+$ ("left-handed") and $T_3(H^{\pm\pm}) = 0$, with the coupling to $\ell_R^-\ell_R'^-$ and $\ell_L^+\ell_L'^+$ ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge

group $SU(2)_L \times SU(2)_R \times U(1)$, the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$

[1] AABOUD 19K search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The search is interpreted in a doublet-triplet extension of the scalar sector with a vev of 0.1 GeV, leading to $B(H^{\pm\pm} \to W^\pm W^\pm) = 1$. See their Fig. 5 for limits on the cross section for $m_{H^{++}}$ between 200 and 700 GeV.

[2] See their Figs. 11(b) and 13 for limits with smaller branching ratios.

[3] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[4] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state.

[5] CHATRCHYAN 12AU search for $H^{++}H^{--}$ production with 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated $H^{++}H^-$ production or assuming different scenarios.

[6] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[7] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^\pm\ell^\pm$ ($\ell,\ell' = e,\mu,\tau$). The limit holds for $\ell = \ell' = \tau$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[8] AAD 21U search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to $B(H^{\pm\pm} \to W^\pm W^\pm) = 1$. See their Fig. 9(a) for limits on the cross section for $m_{H^{++}}$ between 200 and 600 GeV.

[9] AAD 21U search for associated production of $H^{\pm\pm}H^\mp$ followed by the decays $H^{\pm\pm} \to W^\pm W^\pm$, $H^\pm \to W^\pm Z$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. $H^{\pm\pm}$ and $H^\pm$ are assumed to be degenerate in mass within 5 GeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to $B(H^{\pm\pm} \to W^\pm W^\pm) = 1$. See their Fig. 9(b) for limits on the cross section for $m_{H^{++}}$ between 200 and 600 GeV.

[10] SIRUNYAN 21W search for vector boson fusion production of $H^{\pm\pm}$ decaying to $H^{\pm\pm} \to W^\pm W^\pm \to \ell^\pm\nu\ell^\pm\nu$ in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratio for $m_{H^{++}} = 0.2$–3.0 TeV.

[11] SIRUNYAN 19CQ search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^\pm W^\pm \to qq\ell\nu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 0.6 and 2 TeV.

[12] SIRUNYAN 18CC search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 200 and 1000 GeV.

[13] KANEMURA 15 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of ~ 84 GeV can be derived from the same-sign dilepton data of AAD 15AG if H^{++} decays with 100% branching ratio to $W^{(*)}W^{(*)}$.

[14] KHACHATRYAN 15D search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 19.4 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^{++}}$ between 160 and 800 GeV.

[15] KANEMURA 14 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of ~ 60 GeV can be derived from the same-sign dilepton data of AAD 12CY.

[16] AAD 13Y search for $H^{++}H^{--}$ production in a generic search of events with three charged leptons in 4.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[17] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[18] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[19] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[20] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[21] AALTONEN 08AA search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit assumes 100% branching ratio to the specified final state.

[22] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit is for $B(H \to \mu\mu) = 1$. The limit is updated in ABAZOV 12A.

[23] AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.

[24] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[25] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^\pm\mu^\pm$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[26] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^\mp e^\mp H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming $B(H^{\pm\pm} \to \ell^\pm\ell^\pm) = 1$, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[27] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[28] ASAKA 95 point out that H^{++} decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.

[29] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^\pm\ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[30] ACTON 92M from $\Delta\Gamma_Z < 40$ MeV.

[31] SWARTZ 90 assume $H^{\pm\pm} \to \ell^\pm\ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

[1] See their Figs. 12(b) and 14 for limits with smaller branching ratios.

[2] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[3] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state.

[4] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[5] ACHARD 03F search for $e^+e^- \to H^{++}H^{--}$ with $H^{\pm\pm} \to \ell^{\pm}\ell'^{\pm}$. The limit holds for $\ell = \ell' = \tau$, and slightly different limits apply for other flavor combinations. The limit is valid for $g_{\ell\ell'} \gtrsim 10^{-7}$.

[6] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (ℓ,ℓ' = e,μ,τ). the limit holds for ℓ=ℓ'=τ, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[7] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[8] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at $E_{\rm cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[9] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV.

[10] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV.

[11] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.96 TeV. The limit is for B($H \to \mu\mu$) = 1. The limit is updated in ABAZOV 12A.

[12] AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.

[13] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[14] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^{\pm}\mu^{\pm}$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[15] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^{\mp}e^{\mp}H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming B($H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$) = 1, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[16] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[17] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[18] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[19] SWARTZ 90 assume $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (any flavor). The limits are valid for the Higgs-lepton coupling g($H\ell\ell$) $\gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

New Heavy Bosons (W', Z', leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons. The latest unpublished results are described in "W' Searches" and "Z' Searches" reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

W'-Boson Searches

MASS LIMITS for W' (Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\overline{p}$ or $pp \to W'X$ with W' decaying to the mode indicated in the comments. New decay channels (*e.g.*, $W' \to WZ$) are assumed to be suppressed. The most recent preliminary results can be found in the "W'-boson searches" review above.

[1] SIRUNYAN 21Y search for resonances decaying to tb in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 2 for limits on $\sigma \cdot B(W' \to tb)$.

[2] AAD 20AJ search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$. See their Fig. 6 for limits on $\sigma \cdot B$.

[3] AAD 20AT search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3900$ GeV for $g_V = 1$. See their Fig. 13 for limits on $\sigma \cdot B$.

[4] AAD 20T search for W' with SM-like couplings in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4(c) for limits on the product of the cross section, acceptance, and branching fraction.

[5] SIRUNYAN 20AI limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV.

[6] SIRUNYAN 20Q search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.

[7] AABOUD 19B search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. See their Figs. 7 and 8 for excluded regions in $M_{W_R} - M_N$ plane.

[8] AABOUD 19E search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limit on on $\sigma \cdot B$.

[9] AAD 19C search for W' with SM-like couplings in pp collisions at $\sqrt{s} = 13$ TeV. Bosonic decays and $W - W'$ interference are neglected. The limits on e and μ separately are 6.0 and 5.1 TeV respectively. See their Fig. 2 for limits on $\sigma \cdot B$.

[10] AAD 19D search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3400$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 3800$ GeV and $M_{W'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[11] SIRUNYAN 19AY limits shown for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 5 for limits on $\sigma \cdot B$. Limits in the context of a nonuniversal gauge interaction are shown in Fig. 7. Model independent limits on $\sigma B A \epsilon$ can be seen in Fig. 8.

[12] SIRUNYAN 19CP present a statistical combinations of searches for W' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit becomes $M_{W'} > 4500$ GeV for $g_V = 3$ and $M_{W'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[13] SIRUNYAN 19I search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV if we assume $M_{W'} = M_{Z'}$.

[14] AABOUD 18AF give the limit above for right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. These limits also exclude W bosons with left-handed couplings with masses below 2.9 TeV, at the 95% confidence level. $W' \to \ell\nu_R$ is assumed to be forbidden. See their Fig.5 for limits on $\sigma \cdot B$ for both cases of left- and right-handed W'.

[15] AABOUD 18AI search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2670$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2930$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[16] AABOUD 18AK search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV for $g_V = 1$.

[17] AABOUD 18AL search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$.

[18] AABOUD 18BG limit is for W' with SM-like couplings using pp collisions at $\sqrt{s} = 13$ TeV. Bosonic decays of W' and $W - W'$ interference are neglected. See Fig. 2 for limits on $\sigma \cdot B$.

[19] AABOUD 18CH search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2260$ GeV for $g_V = 1$.

[20] AABOUD 18F search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 3500$ GeV and $M_{W'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[21] AABOUD 18K limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 4 for limit on $\sigma \cdot B$.

[22] SIRUNYAN 18 limit is for right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. $W' \to \ell\nu_R$ decay is assumed to be forbidden. The limit becomes $M_{W'} > 3.4$ TeV if $M_{\nu_R} \ll M_{W'}$. See their Fig. 5 for exclusion limits on W' models having both left- and right-handed couplings.

[23] SIRUNYAN 18AX search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. See their Fig.6 for limits on $\sigma \cdot$ B.

[24] SIRUNYAN 18AZ limit is derived for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. No interference with SM W process is considered. The bosonic decays are assumed to be negligible. See their Fig.6 for limits on $\sigma \cdot B$.

[25] SIRUNYAN 18BK search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3100$ GeV for $g_V = 1$.

[26] SIRUNYAN 18BO limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV.

[27] SIRUNYAN 18CV search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. The quoted limit is for $M_N = M_{W_R}/2$. See their Fig. 6 for excluded regions in the $M_{W_R} - M_N$ plane.

[28] SIRUNYAN 18DJ search for resonances decaying to WZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2270$ GeV for $g_V = 1$.

[29] SIRUNYAN 18ED search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2900$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[30] SIRUNYAN 18P give this limit for a heavy-vector-triplet W' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{W'} > 3800$ GeV.

[31] AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for a W' boson having axial-vector SM couplings and decaying to quarks with 75% branching fraction.

[32] AABOUD 17AO search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[33] AABOUD 17B search for resonances decaying to HW ($H \to b\overline{b}$, $c\overline{c}$; $W \to \ell\nu$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 1750$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2310$ GeV and $M_{W'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.

[34] KHACHATRYAN 17J search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into τ and hypothetical heavy neutrino N_τ, with N_τ decaying into τjj. The quoted limit is for $M_{N_\tau} = M_{W_R}/2$. The limit becomes $M_{W_R} > 2350$ GeV (1630 GeV) for $M_{W_R}/M_{N_\tau} = 0.8$ (0.2). See their Fig. 4 for excluded regions in the $M_{W_R} - M_{N_\tau}$ plane.

[35] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.

[36] KHACHATRYAN 17Z limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.

[37] SIRUNYAN 17A search for resonances decaying to WZ with $WZ \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 2400$ GeV and $M_{W'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.

[38] SIRUNYAN 17AK search for resonances decaying to WZ or HW in pp collisions at $\sqrt{s} = 8$ and 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2300$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[39] SIRUNYAN 17H search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. W' is assumed to decay into τ and a heavy neutrino N, with N decaying to $\tau q\overline{q}$. The limit above assumes $M_N = M_{W'}/2$.

[40] SIRUNYAN 17I limit is for a right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. The limit becomes $M_{W'} > 2400$ GeV for $M_{\nu_R} \ll M_{W'}$.

[41] SIRUNYAN 17R search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. Mass regions $M_{W'} < 2370$ GeV and $2870 < M_{W'} < 2970$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are $1000 < M_{W'} < 2500$ GeV and $2760 < M_{W'} < 3300$ GeV for $g_V = 3$; $1000 < M_{W'} < 2430$ GeV and $2810 < M_{W'} < 3130$ GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[42] AABOUD 16AE search for resonances decaying to VV ($V = W$ or Z) in pp collisions at $\sqrt{s} = 13$ TeV. Results from $\nu\nu qq$, $\nu\ell qq$, $\ell\ell qq$ and $qqqq$ final states are combined. The quoted limit is for a heavy-vector-triplet W' with $g_V = 3$ and $M_{W'} = M_{Z'}$.

[43] AABOUD 16V limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.

[44] AAD 16R search for $W' \to WZ$ in pp collisions at $\sqrt{s} = 8$ TeV. $\ell\nu\ell'\ell'$, $\ell\ell q\overline{q}$, $\ell\nu q\overline{q}$, and all hadronic channels are combined. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[45] AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' having SM-like couplings to quarks.

[46] KHACHATRYAN 16AO limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit combines $t \to qqb$ and $t \to \ell\nu b$ events.

[47] KHACHATRYAN 16AP search for a resonance decaying to HW in pp collisions at $\sqrt{s} = 8$ TeV. Both H and W are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.

[48] KHACHATRYAN 16BD search for resonance decaying to HW in pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit is for heavy-vector-triplet (HVT) W' with $g_V = 3$. The HVT model $m_{W'} = m_{Z'} > 1.8$ TeV is also obtained by combining $W'/Z' \to WH/ZH \to \ell\nu b\overline{b}$, $qq\tau\tau$, $qq\overline{b}\overline{b}$, and $qqqqqq$ channels.

[49] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.

[50] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[51] KHACHATRYAN 16O limit is for W' having universal couplings. Interferences with the SM amplitudes are assumed to be absent.

[52] AAD 15AU search for W' decaying into the WZ final state with $W \to q\overline{q}'$, $Z \to \ell^+\ell^-$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[53] AAD 15AV limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[54] AAD 15AZ search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[55] AAD 15CP search for W' decaying into the WZ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[56] AAD 15R limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[57] AAD 15V search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.

[58] KHACHATRYAN 15C search for W' decaying via WZ to fully leptonic final states using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = M_W M_Z/M^2_{W'}$.

[59] KHACHATRYAN 15T limit is for W' with SM-like coupling which interferes the SM W boson constructively using pp collisions at $\sqrt{s} = 8$ TeV. For W' without interference, the limit becomes > 3280 GeV.

[60] KHACHATRYAN 14O search for right-handed W_R in pp collisions at $\sqrt{s} = 8$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. The quoted limit is for $M_{\nu_{eR}} = M_{\nu_{\mu R}} = M_{W_R}/2$. See their Fig. 3 and Fig. 5 for excluded regions in the $M_{W_R} - M_\nu$ plane.

[61] AAD 20AD search for a narrow resonance decaying to a pair of large-radius-jets J_1 and J_2 employing a machine-learning procedure. See their Fig. 3 for limits on $\sigma \cdot B$ depending on assumptions about invariant masses for J_1, J_2, and $J_1 J_2$.

[62] AAD 20W search for W' decaying to WZ' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5(b) for limits on $\sigma \cdot B$ as a function of $m_{Z'}$. The $W' \to WZ'$ branching fraction was chosen to be 0.5 and the mass difference between the W' and Z' was set to 250 GeV.

[63] AABOUD 19BB search for right handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and a boosted hypothetical heavy neutrino N, with N decaying to ℓ and a large radius jet $j = q\overline{q}$. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.

[64] SIRUNYAN 19V search for a new resonance decaying to a top quark and a heavy vector-like bottom partner B decaying to Hb (or a bottom quark and a heavy vector-like top partner T decaying to Ht) in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$.

[65] AABOUD 18AA search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 9 for the exclusion limit in $M_{W'} - \sigma$B plane.

[66] AABOUD 18AD search for resonances decaying to HX ($H \to b\overline{b}$, $X \to q\overline{q}'$) in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 3–5 for limits on $\sigma \cdot$ B.

[67] AABOUD 18CJ search for heavy-vector-triplet W' in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{W'} = M_{Z'}$. The limit becomes $M_{W'} > 5500$ GeV for model with $g_V = 1$.

[68] KHACHATRYAN 17U search for resonances decaying to HW ($H \to b\overline{b}$; $W \to \ell\nu$) in pp collisions at $\sqrt{s}$ = 13 TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $Z' \to HZ$ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-, \nu\overline{\nu}$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[69] AAD 15BB search for W' decaying into WH with $W \to \ell\nu$, $H \to b\overline{b}$. See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.

[70] AALTONEN 15C limit is for a SM-like right-handed W' assuming $W' \to \ell\nu$ decays are forbidden, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. See their Fig. 3 for limit on $g_{W'}/g_W$.

[71] KHACHATRYAN 15V search new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[72] AAD 14AT search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 3a for the exclusion limit in $m_{W'} - \sigma B$ plane.

[73] AAD 14S search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to \ell\ell$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[74] KHACHATRYAN 14 search for W' decaying into WZ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[75] KHACHATRYAN 14A search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to q\overline{q}$, or $W \to q\overline{q}$, $Z \to \ell\ell$. pp collisions data at $\sqrt{s}$=8 TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass−width plane.

[76] AAD 13AO search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to 2j$ using pp collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[77] CHATRCHYAN 13AJ search for resonances decaying to WZ pair, using the hadronic decay modes of W and Z, in pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for the limit on the cross section.

[78] CHATRCHYAN 13AQ limit is for W' with SM-like coupling which interferes with the SM W boson using pp collisions at $\sqrt{s}$=7 TeV.

[79] CHATRCHYAN 13E limit is for W' with SM-like coupling which intereferes with the SM W boson using pp collisions at $\sqrt{s}$=7 TeV. For W' with right-handed coupling, the bound becomes >1850 GeV (>1910 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes >1640 GeV.

[80] CHATRCHYAN 13U search for W' decaying to the WZ final state, with W decaying into jets, in pp collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[81] The AAD 12AV quoted limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s}$=7 TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[82] AAD 12BB use pp collisions data at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[83] AAD 12CK search for $pp \to tW'$, $W' \to \overline{t}q$ events in pp collisions. See their Fig. 5 for the limit on $\sigma \cdot B$.

[84] AAD 12CR use pp collisions at $\sqrt{s}$=7 TeV.

[85] AAD 12M search for right-handed W_R in pp collisions at $\sqrt{s}$ = 7 TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 4 for the limit in the $m_N - m_{W'}$ plane.

[86] AALTONEN 12N search for $p\overline{p} \to tW'$, $W' \to \overline{t}d$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot B$.

[87] CHATRCHYAN 12AR search for $pp \to tW'$, $W' \to \overline{t}d$ events in pp collisions. See their Fig. 2 for the limit on $\sigma \cdot B$.

[88] CHATRCHYAN 12BG search for right-handed W_R in pp collisions $\sqrt{s}$ = 7 TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 3 for the limit in the $m_N - m_{W'}$ plane.

[89] ABAZOV 11H use data from $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model.

[90] ABAZOV 11L limit is for W' with SM-like coupling which interferes with the SM W boson, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. For W' with right-handed coupling, the bound becomes >885 GeV (>890 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes >916 GeV.

[91] AALTONEN 10N use $p\overline{p}$ collision data at $\sqrt{s}$=1.96 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$. See their Fig. 4 for limits in mass-coupling plane.

[92] AALTONEN 09AC search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV.

[93] The ACOSTA 03B quoted limit is for $M_{W'} \gg M_{\nu_R}$, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. For $M_{W'} < M_{\nu_R}$, $M_{W'}$ between 225 and 566 GeV is excluded.

[94] The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. See their Fig. 2 for the limits on the production cross sections as a function of the W' width.

[95] AFFOLDER 01I combine a new bound on $W' \to e\nu$ of 754 GeV, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, with the bound of ABE 00 on $W' \to \mu\nu$ to obtain quoted bound.

[96] ABE 97G search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV.

[97] For bounds on W_R with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.

[98] ABACHI 95E assume that the decay $W' \to WZ$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.

[99] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the W_L-W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] The quoted limit is for manifest left-right symmetric model.

[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[3] PRIEELS 14 limit is from $\mu^+ \to e^+\nu\overline{\nu}$ decay parameter ξ'', which is determined by the positron polarization measurement.

[4] WAUTERS 10 limit is from a measurement of the asymmetry parameter of polarized ^{60}Co β decays. The listed limit assumes no mixing.

[5] ZHANG 08 limit uses a lattice QCD calculation of the relevant hadronic matrix elements, while BEALL 82 limit used the vacuum saturation approximation.

[6] MELCONIAN 07 measure the neutrino angular asymmetry in β^+-decays of polarized ^{37}K, stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the $W_L - W_R$ mixing angle appreciably.

[7] SCHUMANN 07 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing is assumed.

[8] CYBURT 05 limit follows by requiring that three light ν_R's decouple when $T_{dec} > 140$ MeV. For different T_{dec}, the bound becomes $M_{W_R} > 3.3$ TeV $(T_{dec} / 140\ \text{MeV})^{3/4}$.

[9] THOMAS 01 limit is from measurement of β^+ polarization in decay of polarized ^{12}N. The listed limit assumes no mixing.

[10] ACKERSTAFF 99D limit is from τ decay parameters. Limit increase to 145 GeV for zero mixing.

[11] BARENBOIM 98 assumes minimal left-right model with Higgs of $SU(2)_R$ in $SU(2)_L$ doublet. For Higgs in $SU(2)_L$ triplet, m_{W_R} >1100 GeV. Bound calculated from effect of corresponding Z_{LR} on electroweak data through Z–Z_{LR} mixing.

[12] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.

[13] STAHL 97 limit is from fit to τ-decay parameters.

[14] ALLET 96 measured polarization-asymmetry correlation in ^{12}N β^+ decay. The listed limit assumes zero L-R mixing.

[15] KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.

[16] KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed.

[17] BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t=200 GeV and slightly improves for smaller m_t.

[18] SEVERIJNS 93 measured polarization-asymmetry correlation in ^{107}In β^+ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum.

[19] IMAZATO 92 measure positron asymmetry in $K^+ \to \mu^+\nu_\mu$ decay and obtain $\xi P_\mu > 0.990$ (90% CL). If W_R couples to $u\overline{s}$ with full weak strength (V^R_{us}=1), the result corresponds to m_{W_R} >653 GeV. See their Fig. 4 for m_{W_R} limits for general $|V^R_{us}|^2 = 1 - |V^R_{ud}|^2$.

Gauge & Higgs Boson Particle Listings

New Heavy Bosons

[20] POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Supersedes POLAK 91.
[21] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.
[22] COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.
[23] POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Superseded by POLAK 92B.
[24] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
[25] LANGACKER 89B limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.
[26] BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.
[27] JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+.
[28] STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
[29] BERGSMA 83 set limit $m_{W_2}/m_{W_1} > 1.9$ at CL = 90%.
[30] CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from $V-A$ at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{W_R} > 240$ GeV. Assumes a light right-handed neutrino.
[31] BEALL 82 limit is obtained assuming that W_R contribution to K_L^0-K_S^0 mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L-W_R Mixing Angle ζ

Lighter mass eigenstate $W_1 = W_L \cos\zeta - W_R \sin\zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

[1] ACKERSTAFF 99D limit is from τ decay parameters.
[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
[3] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.
[4] MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{\nu}_\mu N \to \overline{\nu}_\mu X$ events at Tevatron, assuming left-handed ν and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1-2m^2_{W_1}/m^2_{W_2}) < 0.0015$. The limit is independent of ν_R mass.
[5] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
[6] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
[7] First JODIDIO 86 result assumes $m_{W_R}=\infty$, second is for unconstrained m_{W_R}.

Z′-Boson Searches

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

Limits for Z'_{SM}

Z'_{SM} is assumed to have couplings with quarks and leptons which are identical to those of Z, and decays only to known fermions. The most recent preliminary results can be found in the "Z'-boson searches" review above.

[1] SIRUNYAN 21N search for resonance decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[2] AAD 20T search for resonances decaying to $b\overline{b}$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7(b) for limits on the product of the cross section, acceptance, b-tagging efficiency, and branching fraction.
[3] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s}$ = 13 TeV.
[4] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[5] AABOUD 18AB search for resonances decaying to $b\overline{b}$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[6] AABOUD 18G search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[7] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig.5 for limits on the Z' coupling strengths with light quarks.
[8] SIRUNYAN 18BO search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.
[9] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[10] KHACHATRYAN 17H search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[11] KHACHATRYAN 17T search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8, 13 TeV.
[12] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.
[13] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[14] KHACHATRYAN 15AE search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.
[15] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.
[16] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.
[17] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 11 for limits in $M_{Z'} - \xi$ plane.
[18] AABOUD 16AA search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[19] AAD 15AM search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.
[20] AAD 13S search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.
[21] CHATRCHYAN 13A use pp collisions at $\sqrt{s}$=7 TeV.
[22] CHATRCHYAN 13AF search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV and 8 TeV.
[23] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.
[24] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.
[25] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[26] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[27] The quoted limit assumes $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$. See their Fig. 4 for limits in mass-coupling plane.
[28] AALTONEN 09AC search for new particle decaying to dijets.
[29] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0026 < \theta < 0.0006$.
[30] ABDALLAH 06C use data $\sqrt{s}$ = 130–207 GeV.

[31] ACOSTA 05R search for resonances decaying to tau lepton pairs in $\overline{p}p$ collisions at $\sqrt{s}$ = 1.96 TeV.

[32] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00422 < \theta < 0.00091$. $\sqrt{s}$ = 91 to 207 GeV.

[33] ABAZOV 01B search for resonances in $p\overline{p} \rightarrow e^+e^-$ at $\sqrt{s}$=1.8 TeV. They find $\sigma \cdot$ B($Z' \rightarrow ee$)< 0.06 pb for $M_{Z'} > 500$ GeV.

[34] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[35] ABREU 00S uses LEP data at $\sqrt{s}$=90 to 189 GeV.

[36] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[37] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0041 < \theta < 0.0003$. ρ_0=1 is assumed.

[38] ABE 97S find $\sigma(Z')\times$B(e^+e^-,$\mu^+\mu^-$)< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[39] VILAIN 94B assume m_t = 150 GeV.

[40] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes B($Z' \rightarrow q\overline{q}$)=0.7. See their Fig. 5 for limits in the $m_{Z'}$–B($q\overline{q}$) plane.

[41] RIZZO 93 analyses CDF limit on possible two-jet resonances.

[42] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix m_W = 80.49 ± 0.43 ± 0.24 GeV and m_Z = 91.13 ± 0.03 GeV.

Limits for Z_{LR}

Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

[1] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0012 < \theta < 0.0004$.

[2] ABE 97S find $\sigma(Z')\times$B(e^+e^-,$\mu^+\mu^-$)< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[3] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \rightarrow Z')\cdot$B($Z' \rightarrow W^+W^-$) to constrain the Z-Z' mixing parameter ξ. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.

[4] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0006$.

[5] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0028$. See their Fig. 14 for limit contours in the mass-mixing plane.

[6] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00098 < \theta < 0.00190$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.

[7] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[8] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[9] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[10] CHAY 00 also find $-0.0003 < \theta < 0.0019$. For g_R free, $m_{Z'} > 430$ GeV.

[11] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.

[12] CASALBUONI 99 discuss the discrepancy between the observed and predicted values of Q_W(Cs). It is shown that the data are better described in a class of models including the Z_{LR} model.

[13] CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta| < 0.0042$.

[14] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0009 < \theta < 0.0017$.

[15] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6.

[16] BARENBOIM 98 also gives 68% CL limits on the Z-Z' mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.

[17] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[18] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[19] RIZZO 93 analyses CDF limit on possible two-jet resonances.

[20] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.

[21] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV. Bounds depend on assumed supernova core temperature.

Limits for Z_χ

Z_χ is the extra neutral boson in SO(10) $\rightarrow$ SU(5) $\times$ U(1)$_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[3] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \rightarrow Z')\cdot$B($Z' \rightarrow W^+W^-$) to constrain the Z-Z' mixing parameter ξ. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.

[4] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[5] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[6] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[7] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[8] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[9] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0011 < \theta < 0.0007$.

[10] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[11] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0016 < \theta < 0.0006$.

[12] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0031$. See their Fig. 14 for limit contours in the mass-mixing plane.

[13] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[14] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00099 < \theta < 0.00194$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.

[15] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >4300 GeV.

[16] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[17] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0017$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[18] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[19] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.
[20] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.
[21] ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_χ.
[22] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0020 < \theta < 0.0015$.
[23] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6.
[24] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.
[25] ABE 97S find $\sigma(Z')\times$B(e^+e^-,$\mu^+\mu^-$)< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.
[26] Z-Z' mixing is assumed to be zero. $\sqrt{s}$= 57.77 GeV.
[27] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.
[28] FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1$ MeV.
[29] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
[30] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim$ 1 MeV).
[31] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

Limits for Z_ψ

Z_ψ is the extra neutral boson in $E_6 \to SO(10) \times U(1)_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] SIRUNYAN 21N search for resonance decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[2] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[3] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[4] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[5] KHACHATRYAN 17T search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8, 13 TeV.
[6] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.
[7] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z')$·B($Z' \to W^+W^-$) to constrain the Z-Z' mixing parameter ξ. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.
[8] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.
[9] KHACHATRYAN 15AE search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.
[10] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.
[11] CHATRCHYAN 13AF search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV and 8 TeV.
[12] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.
[13] CHATRCHYAN 12M search for resonances decaying to e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.
[14] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[15] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[16] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0019 < \theta < 0.0007$.
[17] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[18] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0018 < \theta < 0.0009$.
[19] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0027$. See their Fig. 14 for limit contours in the mass-mixing plane.
[20] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.
[21] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00129 < \theta < 0.00258$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.
[22] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >1100 GeV.
[23] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.
[24] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[25] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.
[26] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0024$.
[27] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.
[28] ABE 97S find $\sigma(Z')\times$B(e^+e^-,$\mu^+\mu^-$)< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.
[29] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.
[30] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.
[31] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim$ 1 MeV).
[32] GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also RIZZO 91.

Limits for Z_η

Z_η is the extra neutral boson in E_6 models, corresponding to $Q_\eta = \sqrt{3/8}\ Q_\chi - \sqrt{5/8}\ Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z')\cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.

[3] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[4] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.

[5] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[6] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[7] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0023 < \theta < 0.0027$.

[8] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[9] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0047 < \theta < 0.0021$.

[10] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0092$. See their Fig. 14 for limit contours in the mass-mixing plane.

[11] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[12] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00447 < \theta < 0.00331$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.

[13] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino $\delta N_\nu < 1$. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >3300 GeV.

[14] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0024$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[15] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[16] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[17] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0062 < \theta < 0.0011$.

[18] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[19] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[20] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[21] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[22] These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim 1$ MeV).

[23] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

[1] SIRUNYAN 21X search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 3500$ GeV for $g_V = 1$.

[2] AAD 20AJ search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. See their Fig. 6 for limits on $\sigma \cdot B$.

[3] AAD 20AM search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limit becomes $M_{Z'} > 4700$ GeV for $\Gamma_{Z'}/M_{Z'} = 0.03$.

[4] AAD 20AT search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 3500$ GeV for $g_V = 1$. See their Fig. 14 for limits on $\sigma \cdot B$.

[5] SIRUNYAN 20Q search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$.

[6] AABOUD 19AS search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. Limits are also set on Z' masses in simplified Dark Matter models.

[7] AAD 19D search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2900$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3800$ GeV and $M_{Z'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[8] SIRUNYAN 19AA search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$.

[9] SIRUNYAN 19CP present a statistical combinations of searches for Z' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit becomes $M_{Z'} > 4500$ GeV for $g_V = 3$ and $M_{Z'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[10] SIRUNYAN 19I search for resonances decaying to ZW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV if we assume $M_{Z'} = M_{W'}$.

[11] AABOUD 18AB search for resonances decaying to $b\bar{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig. 6 for limits on $\sigma \cdot B$. Additional limits on a Z' axial-vector mediator in a simplified dark-matter model are shown in Fig. 7.

[12] AABOUD 18AI search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2650$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{Z'} > 2930$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[13] AABOUD 18AK search for resonances decaying to WW in pp collisions at $\sqrt{s}$ =1 3 TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2750$ GeV for $g_V = 1$.

[14] AABOUD 18B search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 1$. See their Fig.11 for limits on $\sigma \cdot B$.

[15] AABOUD 18BI search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color assisted TC Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limits for wider resonances are available. See their Fig. 14 for limits on $\sigma \cdot B$.

[16] AABOUD 18F search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3500$ GeV and $M_{Z'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[17] SIRUNYAN 18ED search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2900$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[18] SIRUNYAN 18P give this limit for a heavy-vector-triplet Z' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{Z'} > 3800$ GeV.

[19] AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' boson having axial-vector coupling strength with quarks $g_q = 0.2$. The limit is 2100 GeV if $g_q = 0.1$.

[20] AABOUD 17AO search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a Z' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[21] SIRUNYAN 17AK search for resonances decaying to WW or HZ in pp collisions at $\sqrt{s}$ = 8 and 13 TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for g_V =1. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[22] SIRUNYAN 17Q search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a resonance with relative width $\Gamma_{Z'} / M_{Z'} = 0.01$. Limits for wider resonances are available. See their Fig.6 for limits on $\sigma \cdot B$.

[23] SIRUNYAN 17R search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. Mass regions $M_{Z'} < 1150$ GeV and 1250 GeV $< M_{Z'} < 1670$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are 1000 $< M_{Z'} <$ 2500 GeV and 2760 $< M_{Z'} <$ 3300 GeV for $g_V = 3$; 1000 $< M_{Z'} <$ 2430 GeV and 2810 $< M_{Z'} <$ 3130 GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[24] AAD 22 search for $b\bar{b}Z'$ productions in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into $b\bar{b}$. See their Fig.4 for limits on $\sigma \cdot B$.

[25] AAD 21AQ limits are for a $B - L$ gauge boson model derived from their measurements on four-lepton differential cross sections. See their Fig. 13 for exclusion limits on the $B - L$ breaking Higgs boson mass.

[26] AAD 21AZ search for DM mediator Z' produced in association with a SM Higgs boson in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay invisibly $Z' \to \chi\chi$. See their Fig.7 for limits in $M_{Z'} - M_\chi$ plane.

[27] AAD 21BB search for Z' productions in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a SM Higgs boson H and an invisible particle A. See their Fig.7 for limits in $M_{Z'} - M_A$ plane.

[28] AAD 21D set limits on a dark Higgs model with a spin-1 mediator Z' and a scalar dark Higgs boson s. Dark Higgs s is assumed to decay into WW or ZZ. See their Fig.4 for limits in $M_{Z'} - M_s$ plane.

[29] AAD 21K search for $\gamma + \not{E}_T$ events in pp collision at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on Z' particle invisibly decaying to $\chi\chi$.

[30] BURAS 21 performed global fit to leptophilic Z' models using a large number of observables.

[31] CADEDDU 21 obtain limits on Z' coupling $g_{Z'}$ from coherent ν-nucleus scattering data collected by COHERENT experiment. For limits in the $M_{Z'} - g_{Z'}$ plane, see their Figures 3 and 4 for the universal Z' model and Figures 5 and 6 for the $B - L$ model.

[32] COLARESI 21 obtain limits on Z' coupling from coherent ν-nucleus scattering data collected by a Ge detector at the Dresden-II power reactor. See their Fig.7 for limits in mass-coupling plane.

[33] KRIBS 21 set decay-agnostic limits on kinetic mixing parameter between $U(1)_Y$ field and new heavy abelian vector boson (dark photon) field using the HERA ep collision data. See their Fig. 3 for limits in mass-mixing plane.

[34] TUMASYAN 21D search for energetic jets + $\not{E}_T$ events in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a pair of invisible particles $\chi\chi$. See their Fig. 7 for limits on signal strength in $M_{Z'} - M_\chi$ plane, and Fig. 8 for limits on signal strength in quark and dark matter coupling vs mediator mass.

[35] AAD 20AF search for resonances decaying to $H\gamma$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 1c for limits on $\sigma \cdot B$ for the mass range $0.7 < m_{Z'} < 4$ TeV.

[36] AAD 20T search for Dark Matter mediator Z' decaying invisibly or decaying to $q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits in $M_{Z'} - g_q$ plane from the inclusive category. See their Fig. 7(a) for limits on the product of the cross section, acceptance, b-tagging efficiency, and branching fraction from the 2 b-tag category.

[37] AAD 20W search for a Dark Matter (DM) simplified model Z' produced in association with W in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on Z' production cross section.

[38] AAIJ 20AL search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV in the mass regions $M_{Z'} < 60$ GeV, with non-negligible widths considered above 20 GeV. See their Figs. 7, 8, and 9 for limits on $\sigma \cdot B$.

[39] ADACHI 20 search for production of Z' in e^+e^- collisions. The Z' is assume to decay invisibly. See their Fig. 3 and Fig. 5 for limits on Z' coupling and $\sigma(e^+e^- \to e^\pm\mu^\mp Z')$.

[40] SIRUNYAN 20AI search for broad resonances decaying into dijets in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 11 for exclusion limits in mass-coupling plane.

[41] SIRUNYAN 20AQ search for a narrow resonance lighter than 200 GeV decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 3 for limits on Z' kinetic mixing coefficient.

[42] SIRUNYAN 20M search for a narrow resonance with a mass between 350 and 700 GeV in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.3 for exclusion limits in mass-coupling plane.

[43] AABOUD 19AJ search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$ and produced in association with a high p_T photon. For a leptophobic axial-vector Z' in the mass region 250 GeV $< M_{Z'} <$ 950 GeV, the Z' coupling with quarks g_q is constrained below 0.18. See their Fig.2 for limits in $M_{Z'} - g_q$ plane.

[44] AABOUD 19D search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$ and produced in association with a high-p_T photon or jet. For a leptophobic axial-vector Z' in the mass region 100 GeV $< M_{Z'} <$ 220 GeV, the Z' coupling with quarks g_q is constrained below 0.23. See their Fig. 6 for limits in $M_{Z'} - g_q$ plane.

[45] AABOUD 19V search for Dark Matter simplified Z' decaying invisibly or decaying to fermion pair in pp collisions at $\sqrt{s} = 13$ TeV.

[46] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits in the heavy vector triplet model couplings.

[47] LONG 19 uses the weak charge data of Cesium and proton to constrain mass of Z' in the 3-3-1 models.

[48] PANDEY 19 obtain limits on Z' induced neutrino non-standard interaction (NSI) parameter ϵ from LHC and IceCube data. See their Fig.2 for limits in $M_{Z'} - \epsilon$ plane, where $\epsilon = g_q\, g_\nu\, v^2 / (2\, M^2_{Z'})$.

[49] SIRUNYAN 19AL search for a new resonance decaying to a top quark and a heavy vector-like top partner in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on Z' production cross section.

[50] SIRUNYAN 19AN search for a Dark Matter (DM) simplified model Z' decaying to H DM DM in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 7 for limits on the signal strength modifiers.

[51] SIRUNYAN 19CB search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$. For a leptophobic Z' in the mass region 50–300 GeV, the Z' coupling with quarks g'_q is constrained below 0.2. See their Figs. 4 and 5 for limits on g'_q in the mass range $50 < M_{Z'} < 450$ GeV.

[52] SIRUNYAN 19CD search in pp collisions at $\sqrt{s}$=13 TeV for a leptophobic Z' produced in association of high p_T ISR photon and decaying to $q\overline{q}$. See their Fig. 2 for limits on the Z' coupling strength g'_q to $q\overline{q}$ in the mass range between 10 and 125 GeV.

[53] SIRUNYAN 19D search for a narrow neutral vector resonance decaying to $H\gamma$. See their Fig. 3 for exclusion limit in $M_{Z'} - \sigma \cdot B$ plane. Upper limits on the production of $H\gamma$ resonances are set as a function of the resonance mass in the range of 720–3250 GeV.

[54] AABOUD 18AA search for a narrow neutral vector boson decaying to $H\gamma$. See their Fig. 10 for the exclusion limit in $M_{Z'} - \sigma$B plane.

[55] AABOUD 18CJ search for heavy-vector-triplet Z' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{Z'} = M_{W'}$. The limit becomes $M_{Z'} > 5500$ GeV for model with $g_V = 1$.

[56] AABOUD 18N search for a narrow resonance decaying to $q\overline{q}$ in pp collisions at $\sqrt{s} =$ 13 TeV using trigger level analysis to improve the low mass region sensitivity. See their Fig. 5 for limits in the mass-coupling plane in the Z' mass range 450–1800 GeV.

[57] AAIJ 18AQ search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ and 8 TeV in the mass region near 10 GeV. See their Figs. 4 and 5 for limits on $\sigma \cdot B$.

[58] SIRUNYAN 18DR searches for $\mu^+\mu^-$ resonances produced in association with b-jets in the pp collision data with $\sqrt{s} = 8$ TeV and 13 TeV. An excess of events near $m_{\mu\mu} =$ 28 GeV is observed in the 8 TeV data. See their Fig. 3 for the measured fiducial signal cross sections at $\sqrt{s} = 8$ TeV and the 95% CL upper limits at $\sqrt{s} = 13$ TeV.

[59] SIRUNYAN 18G search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} =$ 13 TeV in the mass range 50–300 GeV. See their Fig.7 for limits in the mass-coupling plane.

[60] SIRUNYAN 18I search for a narrow resonance decaying to $b\overline{b}$ in pp collisions at $\sqrt{s} =$ 8 TeV using dedicated b-tagged dijet triggers to improve the sensitivity in the low mass region. See their Fig. 3 for limits on $\sigma \cdot B$ in the Z' mass range 325–1200 GeV.

[61] AABOUD 17B search for resonances decaying to HZ ($H \to b\overline{b}$, $c\overline{c}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with

$g_V = 3$. The limit becomes $M_{Z'} > 1490$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W''}$, the limit increases $M_{Z'} > 2310$ GeV and $M_{Z'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.

[62] KHACHATRYAN 17AX search for lepto-phobic resonances decaying to four leptons in pp collisions at $\sqrt{s} = 8$ TeV.

[63] KHACHATRYAN 17U search for resonances decaying to HZ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W''} > 2$ TeV for $g_V = 3$, in which constraints from the $W' \to HW$ ($H \to b\overline{b}$; $W \to \ell\nu$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[64] SIRUNYAN 17A search for resonances decaying to WW with $WW \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1600$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W''}$, the limit increases $M_{Z'} > 2400$ GeV and $M_{Z'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.

[65] SIRUNYAN 17AP search for resonances decaying into a SM-like Higgs scalar H and a light pseudo scalar A. A is assumed to decay invisibly. See their Fig.9 for limits on $\sigma \cdot B$.

[66] SIRUNYAN 17T search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} =$ 13 TeV in the mass range 100–300 GeV. See their Fig.3 for limits in the mass-coupling plane.
