Abstract

It was believed that, for Riemannian geometry, the satisfaction of Einstein's equivalence principle is equivalent to a proper metric signature, which mathematically implies the existence of local Minkowski spaces. The equivalence principle requires that a "free falling" of an observer must result in a local Minkowski space, whose spatial coordinates are statically attached to the observer, as the local space-time of a spaceship under the influence of only gravity. However, for some Lorentz manifolds, a "free falling" may not result in a statically attached local Minkowski space. In particular, three independent proofs including direct calculations, are provided to show through examples that the Galilean transformation is unequivocally incompatible with the equivalence principle. Therefore, general covariance must be restricted. Moreover, there are unphysical Lorentz manifolds, none of which can be diffeomorphic to a physical space-time, where the physical principles are satisfied. Another result from this analysis is that the time-coordinate must be orthogonal to the space-coordinates if a particle can rest relative to the frame of reference.
"As far as the prepositions of mathematics refer to reality, they are not certain; and as far as they are certain, they do not refer to reality." -- A. Einstein (in 'Geometry and Experience', 1921).

1. Introduction.

A major problem in general relativity is that any Riemannian geometry with the proper metric signature would be accepted as a valid solution of Einstein's equation of 1915. Consequently, many unphysical solutions were accepted as valid [1]. This is, in part, due to the fact that the nature of the source term has been obscure since the beginning [2,3]. When a source term is given, the adequacy of this term for a physical situation is often not clear. For instance, although the electromagnetic energy-stress tensor provides an adequate source term for the Riessner-Nordstrom metric [4,5], its adequacy for gravity involving an electromagnetic wave, is questionable [6,7]. Thus, to determine whether a solution is valid and whether a given source term is adequate, it is necessary to consider general physical requirements.

In general relativity, the most crucial physical requirement is the satisfaction of Einstein's equivalence principle in a physical space [2,3]. Mathematically, however, the equivalence principle can be incompatible with a solution of Einstein's equation, even if it is a Lorentz manifold (whose space-time metric has the same signature as that of the Minkowski space) [7,8]. Unfortunately, some relativists [4,9,10] seem to be unaware of this. Thus, to many theorists, a proper metric signature has become almost a synonym to the satisfaction of the equivalence principle, and they believe incorrectly that this had been proven in mathematics.

To clarify this confusion, let us first review the situation. Physically, the equivalence principle requires that a "free falling" results in a local Minkowski space [3]. Mathematically, although there always exists a local Minkowski space for any point in a Lorentz manifold (which has the proper metric signature), it should be noted that a "free falling" may not always result in a local Minkowski space [8,11]. In other words, while the proper signature of the metric is a mathematical necessity, a "free falling" results in a statically attached local Minkowski space is a physical requirement (§§ 2 & 3).

Einstein proposed that the equivalence principle is satisfied in a physical space-time. Thus, a Riemannian space, where the equivalence principle is not satisfied, is not physically realizable; and in a physically unrealizable "space-time", the equivalence principle cannot be satisfied.
Thus, although defining a coordinate system for the purpose of calculation is only a mathematical step, choosing a space-time coordinate system, which must be physically realizable, requires physical considerations.

Although the equivalence principle does not determine the space-time coordinates, it does reject physical unrealizable coordinate systems. Whereas in special relativity the Minkowski metric limits the coordinate transformations to the Lorentz transformations; in general relativity the equivalence principle limits the coordinate transformations to be among physical space-time coordinate systems. Thus, the role played by the Minkowski metric in special relativity, is extended by the equivalence principle (see also § 6).

The misconception that, in a Lorentz manifold, a "free falling" would automatically result in a local Minkowski space \([12,13]\), has deep-rooted mathematical errors and misunderstandings from believing in the general mathematical covariance in physics (§§ 2–4 & [11]). Thus, to some theorists, it would be necessary to demonstrate this misconception through examples with detailed calculations (see §§ 4–6).

Moreover, there are intrinsically unphysical Lorentz manifolds none of which is diffeomorphic \([4]\) to a physical space-time. Thus, to accept a Lorentz manifold as valid in physics, it is necessary to verify the validity of the equivalence principle in a space-time coordinate system on which physical interpretation can be based. Then, for the purpose of calculation only, any diffeomorphism can be used to obtain new coordinates. It is only in this sense that a coordinate system for a physical space-time can be arbitrary (§§ 4–6).

Note that Einstein's requirement of a mathematical general covariance among all conceivable coordinate systems \([2]\), has been proven to be an over-extended demand \([11]\). (Note that the gauge related to general mathematical covariance, was not accepted by Eddington \([14]\).) To reaffirm this for the skeptics, it will be proved directly that mathematical coordinate systems are not always equivalent in physics (see § 4). Analysis shows that covariance must be restricted by requiring a satisfaction of the equivalence principle (see §§ 4–6). After this necessary rectification, some currently accepted well-known Lorentz manifolds would be exposed as unphysical, although general relativity as a physical theory is unaffected \([11]\).

2. Two Mathematical Theorems in Riemannian Space and Einstein's Equivalence Principle

Now let us discuss two mathematical theorems of Riemannian space \([15,16]\) which are often confused with Einstein's equivalence principle by some mathematicians and theorists. They are:
Theorem 1. Given any point $P$ in any Lorentz manifold (whose metric signature is the same as a Minkowski space) there always exist coordinate systems $(x^j)$ in which $\frac{\partial g_{ab}}{\partial x^j} = 0$ at $P$.

Theorem 2. Given any time-like curve $\Gamma$ there always exist a coordinate system (so-called Fermi coordinates) $(x^i)$ in which $\frac{\partial g_{ab}}{\partial x^i} = 0$ along $\Gamma$.

But, these theorems do not constitute a physical principle since there are insufficient specifics in physics to exclude unphysical situations. From Theorem 1, it is clear that a local Minkowski metric exists at any given point. From Theorem 2, it is claimed \cite{15,16} that the existence of Fermi coordinate implies the existence of freely falling i.e. inertial observers in any Lorenz manifold. It should be noted, however, that here the existence of inertial observers means only local constant metrices but not necessarily local Minkowski spaces.

Although it is possible to transform a local constant metric to a local Minkowski space, such a local Minkowski coordinate system may not necessarily be related to the free falling \cite{3 & 4}.

But, in a physical space, a free falling must result in a local Minkowski space\cite{1}. For instance, the local space-time of a space-ship under the influence of only gravity, is a Minkowski space. Thus, validity of the equivalence principle is needed to ensure that \cite{2} "special theory of relativity applies to the case of the absence of a gravitational field." Einstein \cite{17} pointed out, "As far as the prepositions of mathematics refers to reality, they are not certain; and as far as they are certain, they do not refer to reality."

3. The Restriction of Covariance and the Equivalence Principle

The foundation of general relativity consists of the equivalence principle and covariance. The principle of covariance \cite{2} states that "The general laws of nature are to be expressed by equations which hold good for all systems of coordinates, that is, are covariant with respect to any substitutions whatever (generally covariant)." The covariance principle can be considered as consisting of two features: 1) the mathematical formulation in terms of Riemannian geometry and 2) the general validity of any Gaussian coordinate system as a space-time coordinate system in physics. While feature 1) was eloquently established by Einstein, feature 2) is actually over-extended. The equivalence of all frames of reference simply does not require the equivalence
of all coordinate systems [11]. Eddington [14] pointed out that "space is not a lot of points close together; it is a lot of distances interlocked." Moreover, because of the equivalence principle, it is found that the general mathematical covariance must be restricted [7,8,11].

Kretschmann [18] pointed out that the postulate of general covariance does not make any assertions about the physical content of the physical laws, but only about their mathematical formulation, and Einstein entirely concurred with his view. Pauli [10] pointed out further that "The generally covariant formulation of the physical laws acquires a physical content only through the principle of equivalence, ..." Thus, one has to modify the mathematical general covariance to accommodate the equivalence principle if incompatibility can occur. Einstein [2] argued that "... there is no immediate reason for preferring certain systems of coordinates to others, that is to say, we arrive at the requirement of general co-variance.* This is, of course, incorrect since the equivalence principle is a reason to reject some coordinate systems (see also §§ 5 & 6).

Moreover, a mathematical general covariance requires the indistinguishability between the time-coordinate and a space-coordinate. On the other hand, the equivalence principle is related to the Minkowski space which requires a distinction between the time-coordinate and a space-coordinate. It follows that the mathematical general covariance is inherently inconsistent with the equivalence principle. Thus, the mathematical general covariance must be restricted in physics (see also § 6).

If, at the earlier stage, Einstein's arguments are not so perfect, he seldom allowed such defects be used in his calculations. This is evident in his book, 'The Meaning of Relativity' which he edited in 1954. According to his book and related papers, Einstein's viewpoints on space-time coordinates are:

1) A physical (space-time) coordinate system must be physically realizable (see also 2) & 3) below).

Einstein [19] made clear in 'What is the Theory of Relativity? (1919)' that "In physics, the body to which events are spatially referred is called the coordinate system." Furthermore, Einstein wrote "If it is necessary for the purpose of describing nature, to make use of a coordinate system arbitrarily introduced by us, then the choice of its state of motion ought to be subject to no restriction; the laws ought to be entirely independent of this choice (general principle of relativity)." Thus, Einstein's coordinate system has a state of motion and is usually referred to a physical body. Since the time coordinate is accordingly fixed, choosing a space-time system is not only a mathematical but also a physical step.
2) A physical coordinate system is a Gaussian system such that the equivalence principle is satisfied.

One might attempt to justify the viewpoint of accepting any Gaussian system as a space-time coordinate system by pointing out that Einstein [3] also wrote in his book that "In an analogous way (to Gaussian curvilinear coordinates) we shall introduce in the general theory of relativity arbitrary co-ordinates, \(x_1, x_2, x_3, x_4\), which shall number uniquely the space-time points, so that neighbouring events are associated with neighbouring values of the coordinates; otherwise, the choice of co-ordinate is arbitrary." But, Einstein [3] qualified this with a physical statement that "In the immediate neighbour of an observer, falling freely in a gravitational field, there exists no gravitational field." This statement will be clarified later with a demonstration of the equivalence principle (see eqs. (7) & (8)).

3) The equivalence principle requires not only, at each point, the existence of a local Minkowski space

\[
ds^2 = c^2dt^2 - dX^2 - dY^2 - dZ^2,
\]

but a free falling must result in a local Minkowskian space (see also [5,9,10,20]).

Note that any "free falling" must result in a local Minkowski space, is a physical requirement for a Lorentz metric solution, since Einstein proposed this to be universally valid in any space-time (see § 5).

4. Free Falling and the Equivalence Principle

To clarify the 1916 paper [2], Einstein wrote in his book [3], "According to the principle of equivalence, the metrical relation of the Euclidean geometry are valid relative to a Cartesian system of reference of infinitely small dimensions, and in a suitable state of motion (free falling, and without rotation)." Thus, at each point \((x,y,z,t)\) of a physical space, a "free falling" observer \(P\) must be in a local Minkowski space (1), whose spatial coordinates are statically attached to \(P\), whose motion is governed by the geodesic,

\[
\frac{d^2x^\mu}{ds^2} + \Gamma^\mu_{\alpha\beta} \frac{dx^\alpha}{ds} \frac{dx^\beta}{ds} = 0,
\]

where \(\Gamma^\mu_{\alpha\beta} = (\partial_x \delta_{\alpha\beta} + \partial_y \delta_{\beta\alpha} - \partial_y \delta_{\alpha\beta})g^{\alpha\beta}/2\) and the metric of the space is
Thus, there is a clear physical distinction between a space-coordinate and the time-coordinate. This free falling is equivalent to the existence [9] of "orthogonal tetrad of arbitrarily accelerated observer." In a way, the "free falling" of an observer locally extends the Minkowski space to general relativity. For instance, when a space-ship is under the influence of gravity only, the local space–time is automatically Minkowski, because for a free falling observer, the local Minkowski space is statically attached to the observer.

However, some theorists mistook Einstein's [3] other statements as the equivalence principle. The quotation is "In the immediate neighbourhood of an observer, falling freely in a gravitational field, there exists no gravitational field. We can therefore always regard an infinitesimally small region of the space–time continuum as Galilean. For such an infinitely small region there will be an inertial system (with the space coordinates, \( X_1, X_2, X_3 \), and the time coordinate \( X_4 \)) relatively to which we are to regard the laws of the special theory of relativity as valid." These statements are essentially the mathematical theorems in § 2, although the language is in physics. From these statements, the free falling observer, though in the neighbourhood of a local Minkowski space, may not move with the "inertial system".

However, a possible mathematical choice of coordinates is inadequate in physics, since its realization must be specific. Einstein [2] proposed that the acceleration of the system of reference must be in a free falling with the observer. This observation is echoed by Pauli [10]. He wrote that "For every infinitely small world region, there always exists a coordinate system \( K_0 (X_1, X_2, X_3, X_4) \) in which gravitation has no influence either on the motion of particles or any other physical processes," and that "We can think of the physical realization of the local coordinate system \( K_0 \) in terms of a freely floating, sufficiently small, box which is not subjected to any external forces apart from gravity, and which is freely falling under the action of the latter," and that "It is evidently natural to assume that the special theory of relativity should be valid in \( K_0 \)." Weinberg [5] and Will [20] wrote also some equivalent statements.

Mathematically, the existence of a Local Minkowski space alone implies only that it is possible to construct a Cartesian coordinate system covering an infinitesimal neighborhood of a freely falling observer, i.e., the local space–time of a space–ship under gravity may not be Minkowski. It is the equivalence principle that

\[
ds^2 = g_{\mu\nu}dx^\mu dx^\nu.
\]
ensures its local space-time to be Minkowski. Thus, one must carefully distinguish mathematical properties of a Lorentz metric from physical requirements. Apparently, a discussion on the possibility that the equivalence principle can fail in a Lorentz manifold, was over-looked by Einstein and others (see also § 6).

To see the need of considering beyond the metric signature, we artificially define a Lorentz metric,

$$ds^2 = \alpha^2 dt^2 - dx^2 - dy^2 - dz^2,$$  \hspace{1cm} (4a)

where $\alpha (\geq 2c)$ is a constant. The unit of $t$ is second, the unit of $x, y, \text{or} z$ is centimeter and the unit of $\alpha$ is cm/sec. Metric (4a) is a solution of the Einstein equation $G_{\mu\nu} = 0$. Then, $ds^2 = 0$ would imply that the velocity of light is $\alpha$. One might argue that metric (4a) can be transformed to

$$ds^2 = c^2 dt'^2 - dx'^2 - dy'^2 - dz'^2,$$  \hspace{1cm} (4b)

by the following diffeomorphism,

$$x' = x, \hspace{0.2cm} y' = y, \hspace{0.2cm} z' = z, \hspace{0.2cm} \text{and} \hspace{0.2cm} t' = t\alpha/c.$$  \hspace{1cm} (4c)

Eq. (4c) implies, however, that the units of $t$ and $t'$ are distinct and the light speed remains $\alpha$ but not $c$.

Eq. (4a) is not a rescaling. In a rescaling only the physical units, but not the physics, are changed. For example, the light speed can be expressed as 1 lightyear per year or $3 \times 10^{10}$ cm/sec. However, if $\alpha = 2c$, metric (4a) implies that the light speed would be $2c$, i.e., $6 \times 10^{10}$ cm/sec and metric (4b) implies that the light speed is $3 \times 10^{10}$ cm/half-sec. Thus, if metric (4b) were considered as Minkowski, the diffeomorphism (4c) would amount to redefining the space.

Einstein [3] illustrated his equivalence principle in his calculation of the light bending. (Note, the other method does not have such a benefit.) First, using his field equation of 1915, he justified the linear equation,

$$\frac{\partial^2 y_{\mu\nu}}{\partial x^2} = 2K (T_{\mu\nu} - \frac{1}{2} g_{\mu\nu} T),$$.  \hspace{1cm} (5a)
where \( \gamma_{\mu\nu} = g_{\mu\nu} - \eta_{\mu\nu} \) is the deviation from the flat metric \( \eta_{\mu\nu} \), \( T_{\mu\nu} \) is the energy-stress tensor for massive matter, and \( K \) is the coupling constant. Then, from eq. (5a), he obtained the metric

\[
\text{ds}^2 = c^2(1 - \frac{K}{4\pi G} \int dV_0 \frac{\sigma}{\tau} \text{d}t^2 - (1 + \frac{K}{4\pi G} \int dV_0 \frac{\sigma}{\tau})(\text{dx}^2 + \text{dy}^2 + \text{dz}^2). \tag{5b}
\]

by using the asymptotically flat of the metric. (Note that eq. (5a) can be justified with physical considerations [21], which are independent of the Einstein equation.)

Now, although \( d^2 x^j / ds^2 \neq 0 \), consider an observer \( P \) at \((x_0, y_0, z_0, t_0)\) in a "free falling" state of

\[
\frac{dx}{ds} = \frac{dy}{ds} = \frac{dz}{ds} = 0. \tag{6}
\]

According to the equivalent principle and eq. (1), state (6) of \( P \) implies at \((x_0, y_0, z_0, t_0)\)

\[
c^2(1 - \frac{K}{4\pi G} \int dV_0 \frac{\sigma}{\tau})\text{d}t^2 = \text{ds}^2 = c^2 \text{d}T^2 \tag{7}
\]

since the local coordinate system is attached to the observer \( P \) (i.e., \( dX = dY = dZ = 0 \) in eq. [1]). Because the space coordinates are orthogonal to \( dt \), at \((x_0, y_0, z_0, t_0)\) one has [3]

\[
(dx^2 + dy^2 + dz^2)(1 + \frac{K}{4\pi G} \int dV_0 \frac{\sigma}{\tau}) = (dX^2 + dY^2 + dZ^2) \tag{8}
\]

In general relativity, the law of the propagation of light is characterized by the light-cone condition,

\[
\text{ds}^2 = 0. \tag{9}
\]

Then, the velocity of light is expressed in our selected coordinates by

\[
\left[\sqrt{\frac{dx^2 + dy^2 + dz^2}{dt^2}}\right]_0^1 = c(1 - \frac{K}{4\pi G} \int dV_0 \frac{\sigma}{\tau}). \tag{10}
\]
Einstein wrote \[3\] "We can therefore draw the conclusion from this, that a ray of light passing near a large mass is deflected." Thus, Einstein has demonstrated that the equivalence principle requires that a space-time coordinates system must have a physical meaning; and a space-time coordinate system cannot be just any Gaussian coordinate system. It seems, Einstein chose this calculation method to clarify his statements on the equivalence principle which may be presented somewhat ambiguously in 1916 \[2\].

Although Einstein emphasized the importance of satisfying the equivalence principle, he did not emphasize that this satisfaction is automatically only in a physical space-time. However, there are many ways to go wrong. For instance, if the requirement of asymptotically flat were not used, one could obtain a solution which does not satisfy the equivalence principle. This illustrates also that to see whether the equivalence principle is satisfied, one must consider beyond the Einstein equation (see § 5).

Moreover, if the metric did not satisfy the equivalence principle, $ds^2 = 0$ would lead to an incorrect light velocity because the manifold is not a physical space-time. In addition, Einstein's calculational approach would lead to contradictory results. To illustrate these, it will be shown in next section that an arbitrary Gaussian system as a space-time coordinate would lead to theoretical inconsistency and errors in physics.

5. Validity of a Metric in Physics and the Equivalence Principle

A given metric defines a physical space only if the space-time coordinate system is physically realizable, i.e., the equivalence principle is satisfied. This will be illustrated by a few examples of metric spaces. For clarity and simplicity, we discuss cases without gravitational forces.

Example 1, consider the metric (4) again. If the equivalence principle were valid, one would obtain

$$c^2 dt^2 = g_{ij} dx^i dx^j, \quad \text{and} \quad (dx^2 + dy^2 + dz^2) = (dx_1^2 + dy_1^2 + dz_1^2), \quad (11a)$$

for a resting observer at a point $(x_0, y_0, z_0, t_0)$. Eq. (11a) and $ds^2 = 0$ imply that the light speed is

$$\left[\frac{dx^2 + dy^2 + dz^2}{c dt}\right]^{1/2} = \left[\frac{dx_1^2 + dy_1^2 + dz_1^2}{c dt}\right]^{1/2} = 1 \quad (11b)$$
Eq. (11b) implies, however, that the light speed is \( c \) in the local Minkowski coordinate, but is \( a (\geq 2c) \) in the \((x, y, z, t)\) space. But, since there is no gravitational force for this case, we can have also

\[
x = X, \quad y = Y, \quad \text{and} \quad z = Z
\]

Eqs. (11) and (12) absurdly mean that for the same frame of reference, we have different light speeds. This certainly disagrees with Einstein's statement [19] that "In physics, the body to which events are spatially referred is called the coordinate system". In summary, metric (4) is not physically realizable.

Example 2, consider the transformation, which is a diffeomorphism,

\[
t = C \left\{ \exp(T/C) - \exp(-T/C) \right\} / 2.
\]  

(13a)

Then

\[
ds^2 = \frac{1}{4} \left\{ \exp(T/C) + \exp(-T/C) \right\}^2 dT^2 - dx^2 - dy^2 - dz^2
\]

(13b)

represents the Minkowski metric after the transformation. If metric (13b) is realizable, according to \( ds^2 = 0 \), the measured light speed would be \( \left\{ \exp(T/C) + \exp(-T/C) \right\} / 2 \).

From (13b), the Christoffel symbols \( \Gamma_{\alpha\beta\gamma} = \left\{ \theta_{\alpha\beta\gamma} + \theta_{\gamma\beta\alpha} - \theta_{\alpha\gamma\beta} \right\} / 2 \), are zeros except

\[
\Gamma_{ttt} = \frac{\theta_{ttt}}{2}
\]

(14)

Then, according to the geodesic equation, the equation of motion for a particle at \((x, y, z, T)\) is

\[
d^2T/ds^2 + \Gamma_{tt}^T dT/ds = 0, \quad \text{and} \quad d^2x/ds^2 = d^2y/ds^2 = d^2z/ds^2 = 0
\]

(15)

where

\[
\Gamma_{tt}^T = \frac{d}{dT} \left( \ln \left\{ \exp(T/C) + \exp(-T/C) \right\} \right)
\]

It follows eq. (15) that one obtains, for some constant \( k \)

11
\[
\frac{dT}{ds} = k \{\exp(T/C) + \exp(-T/C)\}^{-1} \quad \text{and} \quad \frac{dx^{\mu}}{ds} = \text{constant} \quad (16)
\]

Now, consider the case \(dx/dT = dy/dT = dz/dT = 0\); and therefore \(dx/ds = dy/ds = dz/ds = 0\). Thus, in such a "free falling", there is no change in the spatial position nor acceleration. Physically, this means that such an observer would have the same frame of reference, whether "free falling" or not. Thus, he would absurdly have two different light speeds from the same frame of reference, if the equivalence principle were satisfied.

According to Einstein, the equivalence principle is not satisfied and metric (13) is not realizable.

Now, to see further that the equivalence principle is needed for the theoretical consistency of general relativity, let us consider Example 3, a frame of reference \(K'\) with a constant Lorentz metric,

\[
ds^2 = \left[ dz' + (c - v)dt' \right] \left[ -dz' + (c + v)dt' \right] - dx'^2 - dy'^2, \quad (17)
\]

since any constant metric satisfies the Einstein equation \(G_{\mu\nu} = 0\). Then, for light rays in the \(z'\)-direction, \(ds^2 = 0\) would imply at any point the light speeds were

\[
\frac{dz'}{dt'} = c + v, \quad \text{or} \quad \frac{dz'}{dt'} = -c + v. \quad (18)
\]

Clearly, eq. (18) also does not give a correct light speed since (18) also violates coordinate relativistic causality, i.e. no cause event can propagate faster than the velocity of light in a vacuum. Thus, metric (17) is not physically realizable, and those in (18) cannot be regarded as coordinate velocities.

Moreover, according to the geodesic equation (2), metric (17) implies \(d^2x^{\mu}/ds^2 = 0\), and thus

\[
\frac{dx^{\mu}}{ds} = \text{constant,} \quad \text{where} \quad x^{\mu} = (x', y', z', or t') \quad (19)
\]

at any point. Now, according to metric (17), consider the case of "free falling" at \((x_0', y_0', z_0', t_0')\)

\[
dx'/ds = dy'/ds = dz'/ds = 0, \quad \text{and} \quad dt'/ds = (c^2 - v^2)^{1/2}. \quad (20)
\]
Note that since there is no acceleration nor any change in the spatial position, such a "free falling" observer carries with him the frame of reference $K'$. But, the $K'$ metric (17) is not a Minkowski space.

Nevertheless, mathematics ensures the existence of a local Minkowski space, which can be obtained by choosing first the path of a particle to be the time coordinate and then the other three space coordinates by orthogonality. Let us investigate this scenario. According to condition (20), the time coordinate would remain the same $dt'$. But, the coordinate $dz'$ is not orthogonal to $dt'$. In order to have three orthogonal space coordinates to form a local Minkowski space, it is necessary to transform $dz'$ by

$$dT = dt', \; dX = dx', \; dY = dy', \text{ and } dZ = dz' - vdt'. \tag{21}$$

But, since the observer at $(x_0, y_0, z_0, t_0)$ is in a state of $dz' = 0 \; (i.e., \; dZ \neq 0)$, this local system is not statically attached to the observer, and hence is unrelated to the "free falling". Thus, the equivalence principle is not applicable to Lorentz manifold (17). Nevertheless, at any space–time point, it is always possible to have a local Minkowski coordinate system which is related to a free falling and therefore Yu (p. 42 of [13]) is incorrect. This illustrates that not only the existence of a local Minkowski space, but also how such a local space is related to the geodesic, is crucial for a physical space.

It has been shown in three different approaches that metric (17) is incompatible with the equivalence principle and therefore physically unrealizable. Also, (21) is clearly a Galilean transformation. Thus, it has been shown that the Galilean transformation is also not valid in general relativity. The failure of satisfying the equivalence principle should be expected since the Galilean transformation is experimentally not realizable.

6. The Equivalence Principle, Covariance, and Intrinsically Unphysical Lorentz Manifolds

The foundation of general relativity consists of the equivalence principle and covariance. However, the principle of general relativity requires only the equivalence of all frames of reference, but not all mathematical coordinate systems as claimed [22]. A distinction between time and space is inherent, as Hawking [23] pointed out that "something that distinguished the past from the future, giving a direction to time." The equivalence principle is a physical requirement for a valid physical space–time coordinate system.
In terms of mathematics, the satisfaction of the equivalence principle is the feasibility of a coordinate transformation which is subjected to the geodesic. The trajectory of a particle may relate to the metric in a manner depending the coordinate system. Also, a local coordinate system is restricted by the non-covariant requirement of being a Minkowski metric with spatial orthogonal coordinates statically attached to the geodesic. These would put a severe restriction on the possible Gaussian coordinate systems.

Thus, the equivalence principle is related to the physical meaning of the coordinates in a space-time coordinate system. For instance, as shown by metric (10), the metric element $g_{tt}$ cannot be arbitrary. Moreover, the trajectory of a particle, being also the local time, is orthogonal to the local spatial coordinates. This means, however, when the "time" coordinate is not orthogonal to the "space" coordinates, the equivalence principle is not satisfied if a particle is allowed to rest relative to the frame of reference.

Let us illustrate this by revisiting metric (17). Consider the Galilean transformation

$$t = t', \quad x = x', \quad y = y', \quad \text{and} \quad z = z' - vt'. \quad (22a)$$

Then

$$ds^2 = c^2 dt^2 - dx^2 - dy^2 - dz^2, \quad (22b)$$

is obtained from metric (17). Now, at $(x,y,z,t)$ the state (20) now becomes

$$\frac{dx}{ds} = \frac{dy}{ds} = 0, \quad \frac{dz}{ds} = -vt', \quad \text{and} \quad \frac{dt}{ds} = (c^2 - v^2)^{-\frac{1}{2}}. \quad (23)$$

The trajectory of the particle has the direction $(0,0,dz,dt)$, and its orthogonal vector is $(0,0,dt,dz^2)$. Thus, the local Minkowski space can be obtained by a Lorentz transformation, which preserves orthogonality.

On the other hand, from metric (17) the direction of the particle is $(0,0,0,dt')$ and its orthogonal vectors are $(1,0,0,0), (0,1,0,0)$ and $b_1 = (0,0,\alpha,\beta)$ where $\alpha^2 = 1 - v^2/c^2$, and $\beta = -v/c^2\alpha$. However, since the state of $(0,0,0,dt')$ requires $dz' = 0$, but $dt' \neq 0$, the vector $b_1$ is not statically attached to the particle. This is due to the fact that the local space $(dx',dy',dz')$ which is fixed to the particle is not orthogonal to the the vector $(0,0,0,dt')$. This means that metric (17) is not physically realizable.
In the above analysis, it has been illustrated that the Galilean transformation is incompatible with the equivalence principle in the absence of gravity. In fact, the incompatibility is also true even when gravity is present. To illustrate this, let us consider metric (5b) and the physical situation that a particle at \((0,0,z_0,t_0)\) moving with velocity \(v\) at the \(z\)-direction. The Galilean transformation (22a) transforms metric (4b) to

\[
\begin{aligned}
\text{ds}^2 &= c^2\left(1 - \frac{\mathbf{K}}{4\pi} \int \mathbf{dV} \frac{\mathbf{\Gamma}}{r^3}\right) \text{d}t^2 - \left(1 + \frac{\mathbf{K}}{4\pi} \int \mathbf{dV} \frac{\mathbf{\Gamma}}{r^3}\right) \left(\text{d}x^2 + \text{d}y^2 + \text{d}z^2 - v \text{d}t^2\right). \\
\end{aligned}
\] (24)

If metric (24) had a physical realizable coordinate system \(S'\), the particle would be at \((0,0,z_0',t_0')\) in the state \((0,0/0/dt')\) and the local spatial coordinates \(dx', dy',\) and \(dz'\) would be statically attached to the particle at the instance \(t_0'\). However, according to metric (24), the coordinate \(dz'\) is not orthogonal to \(dt'\).

But, in a local Minkowski space, \(dt'\) would be orthogonal to a statically attached three dimensional linear subspace. This is not possible because \(dx', dy',\) and \(dz'\) can form a basis of a three dimensional subspace. Thus, the equivalence principle cannot be satisfied and metric (24) is not a physically realizable space. An interesting result from this analysis is that, due to the equivalence principle, the time-coordinate must be orthogonal to the space-coordinates if a particle is allowed to rest relative to the frame of reference.

Moreover, a Lorentz manifold may not be diffeomorphic to a physical space. Even a solution of Einstein’s equation can be intrinsically unphysical if it fails physical requirements. For instance, consider

\[
\begin{aligned}
\text{ds}^2 &= \text{du} \text{dv} + h_{\mu}(u) x^i x^i \text{du}^2 - \text{dx}^i \text{dx}^i, \\
\end{aligned}
\] (25)

where \(u = t - z, v = t + z, h_{\mu}(u) \geq 0,\) and \(h_{\mu} = h_{\mu}^{\mu}.\) Its physical cause can be an electromagnetic plane wave [24]. Metric (25) does not satisfy coordinate relativistic causality and therefore the equivalence principle because the requirement, \(1 \geq (1 + H)/(1 - H)\) (where \(H = h_{\mu} x^i x^i\)), may not be satisfied. (Note, that metric (25) does not satisfy the equivalence principle, can also be shown as previously by direct calculations.)

Furthermore, this metric is incompatible with Einstein’s notion of weak gravity and the correspondence principle since \(H\) can be arbitrarily large. The gravitational force (related to \(\Gamma^t_t = \epsilon /\hbar (h_{\mu} x^i x^i) /\text{d}t\) has arbitrary parameters (the coordinate origin). This arbitrariness in the metric violates the principle of causality.
(i.e., the causes of phenomena are identifiable) \cite{8,11}. Although \eqref{25} is a Lorentz metric, it cannot be
diffeomorphic to a physical space since a diffeomorphism cannot eliminate any parameter.

7. Conclusions and Discussions

The Minkowski metric in special relativity is a special case of the metric in general relativity. However,
it was not clear that all the principles which lead to general relativity are compatible with each other in this
special case. For instance, the equivalence principle can be considered as a generalization of the Minkowski
metric, but this principle may not be compatible with the covariance principle. In fact, there is no physical
need to extend the space–time physical coordinate system to an \textit{arbitrary} Gaussian system \cite{11}.

Although the creation of general relativity is due to the desire to have a theory of gravity which is
consistent with special relativity, the consistency between special relativity and general relativity has not been
thoroughly checked. Note that, to establish special relativity, the Galilean transformation is proven to be
physically \textit{unrealizable} by experiments. Thus, a Galilean transformation cannot be compatible with the equi­
valence principle which is applicable to only a physical space. This means that the equivalence of all frames
of reference is not the same as the physical equivalence of all mathematical coordinate systems. In particular,
due to the equivalence principle, the Minkowski metric is the \textit{only} physical constant space–time metric.

A Galilean transformation clearly leads to a violation of the equivalence principle that $ds^2 = 0$ would
imply a light "velocity" larger than $c$ \cite{11}. However, due to entrenched misconceptions \cite{12,13}, this pro­
blem was not even recognized for further investigations. Instead, strong denial in terms of false arguments
was supported with misunderstandings in physics and/or erroneous statements in mathematics. Thus, it is
necessary to calculate examples which directly demonstrate a violation of the equivalence principle.

Moreover, some "Theorists" actually distort Einstein's equivalence principle to fit the mathematical
theorems (see §§ 3 & 4) because they are unable to tell the difference between mathematics and physics.
However, unlike mathematics, physics is restricted by the physical reality. The fact that the \textit{local space–
time of a spaceship under the influence of only gravity, is a Minkowski space requires that a
free falling must result in a local Minkowski space}. As stated by Einstein, the equivalence principle
is necessary to ensure that \cite{2} "special theory of relativity applies to the case of the absence of a gravita–
tional field." Thus, nature unequivocally defeats any attempt to misinterpret the equivalence principle.

Einstein proposed the equivalence principle for physics [2,3]. It was misunderstood that the equivalence principle is always applicable to a Lorentz manifold [9,13,20]. However, for some of such metric spaces, a local Minkowski space may not be obtained in a "free falling". Apparently, Einstein's quotation (1921) at the beginning of this paper is valid not only for Euclidean geometry but also for Riemannian geometry.

Mathematically, a local Minkowski space for an hypothetical observer is obtained as follows:

1) Choose the path of a "free falling" hypothetical observer to be the local time coordinate.

2) Choose the other three space coordinates by orthogonality.

Thus, a local Minkowski space can always be constructed for any hypothetical observer. But, the so chosen spatial coordinates may not be statically attached to the hypothetical observer. In other words, the mathematically constructed local Minkowski space may be unrelated to the "free falling" (§ 5). Thus, in contrast to the suggestion of Misner et al. [9], an existence of the tetrad in a Riemannian space, is not always possible.

The fact that there is a distinction between the equivalence principle and the proper metric signature would imply also that the covariance principle must be restricted. However, general relativity as a physical theory is unaffected by the restriction due to the equivalence principle. An important function of the equivalence principle test is to eliminate intrinsically unphysical Lorentz manifolds, any of which cannot be diffeomorphic to a physical space (see § 6 and also [11]).

Since a Lorentz manifold may not satisfy the equivalence principle, further considerations must be made for its valid applicability. For instance, since the principle of equivalence implies relativistic causality, a physical space must satisfy relativistic causality. When gravity is present, the light speed is smaller than maximum speed c due to the gravitational effects of space contraction and time dilation. Therefore, coordinate relativistic causality (i.e., the light speed c is the maximum velocity of propagation for any event) can be used as a convenient criterion. For example, coordinate relativistic causality is satisfied by the exterior Schwarzschild solution [11]. The principle of causality (i.e., the causes of phenomena are identifiable) necessitates the asymptotic flatness of a metric due to an isolated source. However, these necessary conditions may not assure the theoretical validity of the equivalence principle in a metric space.

Perhaps, due to a confusion in understanding Einstein's equivalence principle, this principle is not exp-
lained adequately in some text books [4,13,16,25]; and theorists such as Synge [16] even advocated that
the basis of general relativity should be the Einstein field equation alone rather than the equivalence principle.
However, theoretically there is no satisfactory proof of rigorous validity of Einstein's field equation [26].
Experimentally, the validity of Einstein's equation has not yet been established beyond doubt [27]. In fact,
the invalidity of Einstein's equation for two-body problems was conjectured by Hogarth [28] in 1953; and
Einstein himself had pointed out that his equation may not be valid for matter of very high density [3].
Moreover, it has been proven experimentally that Einstein's equation must be modified [21].

But, the equivalence principle remains indispensable because of its solid experimental foundation [20,
21]. Thus, as Weinberg [5] points out, "it is much more useful to regard general relativity above all as a
theory of gravitation, whose connection with geometry arises from the peculiar empirical properties of
gravitation, properties summarized by Einstein's Principle of the Equivalence of Gravitation and Inertia."

8. Acknowledgements

This paper is dedicated to Professor P. Morrison, who suggested this problem, for fruitful discussions
over years. The author gratefully acknowledges stimulating discussions with Professors C. L. Cao, Li-Zhi
H. Yilmaz, Yu Yun-jiang, and Y. Z. Zhang. This work is supported in part by Innotec Design, Inc., U.S.A.

ENDNOTES

1) A local Minkowskian space is a short hand to express that special relativity is locally valid, except for
phenomena involving the space-time curvature.
