### DCA312 Shell Gauge Data During Welding Operation

Prior to shell welding, strain gauges were mounted on the shell of DCA312 at the locations shown in Fig. 1. Data were collected during the closure and energization of the press, after each weld pass, and as the press was opened. The measured strain changes, without use of the compensating gauges, is shown in Table I. Compensating gauge C1 failed when the press was first closed and its data are not shown. Between the second and third data set the yoking press was closed by lowering the upper platen until it was supported by the magnet. Although the hydraulic pressure listed in column 1 is zero, it is apparent that a considerable load is present due to the weight of the platen and tooling.

Figure 2 plots the data sequentially. As the press is first closed and then energized, the shell is caused to conform to the yoke and irregularities in the local radius of curvature of the shell are brought closer to the radius of the yoke. This causes local bending of the shell which causes some gauges to show positive and some to show negative strain changes. Then the shell is welded and after each weld pass there is an increase in the strain measured by most gauges. Then as the press is opened there is a modest redistribution of the stresses.

Figure 3 shows the strain changes in each gauge as a function of press load during the initial energization. The offsets result from the load due to the weight of the press platen. The gauges at the same azimuth at each end of the magnet track each other reasonably well indicating that the structure of local radius of curvature of the shell is the same along its length. The compensating gauges shows a non-zero effect of press load, but this effect is small compared with the active gauges.

Figure 4 is a plot of the strain change due to closure and loading of the press as a function of angular distance from the weld. Figure 5 shows the change due to welding. This change is a combination of tensile stress and local bending as the azimuthal tension causes the shell to conform further to the shape of the yoke. The bending effects should be of the same sign as those observed during press closure; for example the high point at 28 degrees in Figure 5 appears also in Figure 4. The circles in Figure 5 are plotted by arbitrarily subtracting the average of the two strains at each azimuth in Figure 4 from those in Figure 5. The data suggest that the strain near the weld, is approximately 1500 - 2000 microstrain, corresponding to a stress of 45 - 60 kpsi. Far from the weld the stress is much lower due to friction between the shell and the yoke and tooling[1]. The gauges at 61 degrees show essentially no strain change, either with press closure (dominantly bending) or welding (tension plus bending). That the gauges at both ends behave in the

same manner suggests that this is not an instrumental effect. It is difficult to understand this behavior as there are no irregularities in the yoke surface in this region.

Figure 6 shows the strain change as the press is opened. As the press load is removed the frictional force (proportional to the radial force between the shell and the yoke and tooling) decreases and the shell stress redistributes. As expected[1] there is a reduction of the stress (by several kpsi) near the weld and a comparable increase far from the weld.

# 50MM DIPOLE SKIN STRAIN GAGE PLACEMENT

## NOTES:

1. DIMENSIONS ARE RADIAL, FROM CENTER OF ALIGNMENT KEY TO CENTER OF STRAIN GAGE.
2. GAGES LABELED "A" ARE ACTIVE GAGES MEASURING STRAIN IN THE AZIMUTHAL DIRECTION, GAGES LABELED "C" ARE COMPENSATING GAGES.
3. COMPENSATING GAGE C3 IS TO BE PLACED BETWEEN ACTIVE 3 AND 4.
4. ONE COMPENSATING BLOCK TO BE WELDED.
5. GAGES AND WIRES MUST FIT WITHIN A 50. MM(2 INCH) WIDE SLOT CENTERED ON THE GAGE.
