

## DSA326 TEST PLAN

Page 1 of 6

TS-SSC 91- 185

T. Jaffery

9 / 18 /91

### Test Objectives

DSA326 is the fourth 50 mm model SSC dipole magnet to be tested in Lab2. For most part the test plan for this magnet is similar to previous standard test procedures for short R&D magnets tested in Lab2. Test objectives for magnet DSA326 are to make the standard quench, strain gage and harmonics measurements through two thermal cycles . Magnetic field measurements will be made both with the standard magnetometer and with HAL2 system. All standard harmonics tests will be done with probe #11. Heater studies will be done during first thermal cycle.

DSA326 instrumentation is similar to magnet DSA324. DSA326 has inner and outer collar, bullet, and skin tension (on the shell of the magnet) gages. Since the cold calibration (Ro) is not available for shell gages, therefore they will be calibrated at 4.3 K in Lab2.

#### Distribution:

S. Delchamps

M. Lamm

## THERMAL CYCLE I

1) Cool to 4.35 K monitoring all thermometers and strain gages at 10 minute logging intervals.

2) Protect magnet with a 30 mohm dump resistor. Delay dump firing 50 msec after quench detection, but phase back power supply promptly. Evacuate the warm bore tube.

3) Check safety circuit balances:

Set data logger sampling frequencies and pre-quench windows:  
all the data loggers at 1 kHz and 50% pre-quench

a) sawtooth ramps between 100 A and 200 A at 50 A/sec.

b) manual trip at 1000 A.

4) Set data logger sampling frequencies and pre-quench windows:

a) data loggers 1 and 2: 2 kHz and 25% pre-quench.

b) data loggers 3 and 4: 5 kHz and 50% pre-quench.

### STRAIN GAGE AND QUENCH TESTING

5) Bring magnet to 4.35 K (860 Torr or 16.5 psia.) Ramp rate = 16 A /sec.

a) Take strain gage runs, one file per current loop, using the sequences of currents below. Take data at all currents on the way up, and for the currents marked "\*" on the way down. For high currents runs the Power Leads flow rate must be >275 SCFH.

Run 1: 0\*, 2200, 3100\*, 3800, 4400\*, 4900, 5400\*, 5800 A,

Run 2: 0\*, 2200, 3100\*, 3800, 4400\*, 4900, 5400\*, 5800, 6200 A

Run 3: 0\*, 2200, 3100\*, 3800, 4400\*, 4900, 5400\*, 5800, 6200\*, 6600 A

Run 4: 0\*, 2200, 3100\*, 3800, 4400\*, 4900, 5400\*, 5800, 6200\*, 6600, 7000 A

Run 5: 0\*, 2200, 3100\*, 3800, 4400\*, 4900, 5400\*, 5800, 6200\*, 6600, 7000\*,  
7400 A

Run 6: 0\*, 2200, 3100\*, 3800, 4400\*, 4900, 5400\*, 5800, 6200\*, 6600, 7000\*,  
7400 A, 8100 A

Note: Runs 5 and/or 6 may lead to first spontaneous quench .

6) With ramp rate = 16 A/sec, train the magnet until 4 plateau quenches have occurred. Do not do more than 15 quenches. The predicted short sample limit currents (inner coil) as a function of temperature are:

7) Take a strain gage run to  $I_{\text{plateau}} - 100$  A.

### 4.2K STUDIES

8) Bring the magnet to 4.2K. Keep the bore tube evacuated and establish plateau  $I_{\text{quench}}$  .

b) Bring the warm bore tube to room temperature, and establish the flow of room temperature purge gas. Quench the magnet twice, or to plateau current if any training is observed, to establish  $I_{\text{quench}}$  under these conditions.

## HARMONICS MEASUREMENTS

9) Bring the warm bore tube to room temperature, insert probe #11, and establish the flow of room temperature purge gas. Quench the magnet twice, or to plateau current if any training is observed, to establish  $I_{\text{quench}}$  under these conditions.

10) Measure harmonics at 4.2 K.

a) Power the magnet with 200 A. Locate the ends of the magnet relative to the tape measure on the probe mounting fixture by moving the probe vertically and identifying the points at which the dipole field is 1/2 its central value. Define the magnet center to be half way between the two end points.

b) Ramp the magnet to quench at 16 A/sec.

c) Position the probe 9 inches below (towards return end, away from the gage pack) the center of the magnet and measure the harmonics as a function of current. Do one sawtooth cycle at 16 A/sec from 0 to 6500 A or  $I_{\text{quench}} - 200$  A, whichever is higher. Record data every 6 seconds (approximately every 100 A) starting from 0 A.

d) Ramp the magnet to quench at 16 A/sec.

e) Ramp the magnet at 12 A/sec to 6500 A or  $I_{\text{quench}} - 200$  A, whichever is lower, hold at flat top for 2 minutes, ramp down at -12 A/sec to 110 A, hold for 2 minutes, ramp at 6 A/sec to 5000 A. (If  $I_{\text{quench}} < 5500$  A, the final ramp should be to  $I_{\text{quench}} - 500$  A.)

f) Measure harmonics as a function of position at 5000 A (or  $I_{\text{quench}} - 500$  A.) Take data at the following positions relative to the center of the magnet (positive is towards the lead end, i.e. up.)  $z = -24", -22", -20", -18", -16", -14", -12", -10", -8", -6", -4", -2", 0", 2", 4", 6", 8", 10", 12", 14", 16", 18", 20", 22", 24"$ .

g) Ramp the magnet to 5500 A (or  $I_{\text{quench}} - 200$  A), then back to 5000 A (or  $I_{\text{quench}} - 500$  A.) Measure harmonics as a function of position at  $z = -24", -22", -20", -18", -16", -14", -12", -10", -8", -6", -4", -2", 0", 2", 4", 6", 8", 10", 12", 14", 16", 18", 20", 22", 24"$ .

h) Position the probe 9 inches below (towards return end, away from the gage pack) the center of the magnet and measure the harmonics as a function of current. Ramp the magnet from 5000 A down to 110 A, then to  $I_{\text{quench}} - 200$  A, back to 110 A, then to 1000 A, all at 16 A/sec. Record data every 6 seconds (approximately every 100 A) starting from 500 A on the first down ramp until 1000 A on the second up ramp.

i) **HAL2 Harmonics:** Ramp the magnet to quench at 16 A/sec. Repeat steps e) and f) with the HAL2 System instead of the magnetometer.

## HEATER STUDIES

11) These Studies are described in the appendix of this plan.

## THERMAL CYCLE II

12) Warm the magnet to within 10 K of the pretest temperature (the dewar temperature before it was cooled down the first time.) Record the strain gages and thermometers at 10 minute intervals during the thermal cycle.

13) Repeat steps 2 - 9 and steps 10e-i from the first thermal cycle.

14) RAMP RATE dependence studies at 4.35 K.

a) Ramp to quench at 16, 25, 50, 75, 100, 150, 200, 225, 250, 300 A/sec.

b) Ramp to 6500 A at 16 A/sec, then ramp down from 6500 A to 4000 A at 100, 200, 300, and 400 A/sec.

15) This can be done at 4.2 K or 4.35 K.

DSA323 during its testing had displayed some unusual quenching on the downramp after exceeding 7kA one or more times without quenching. This part has been added to see any down ramp quenching like it was seen on DSA323. Do 6-8 sawtooth ramps from 0 - ( $I_q - 200$ )A with 180 sec dwell time at the peak current (flattop) to observe any down ramp quenches.

## Rawson Lush 789 Fieldmeter

### 16) Transfer Function Measurement

Insert the Rawson Lush 789 Fieldmeter into the bore tube and zero the meter. Ramp the magnet to 500 A and measure the current with HP3457A DVM and field on the probe meter.

Ramp the magnet at 1000 amps interval up to 6500 A or ( $I_q - 200$  A) and take I and field measurement at each interval .

## FURTHER STRAIN GAGE STUDIES

Remove the harmonic probe and evacuate the warm bore.

17) Take the magnet to 3.8 K. Using 16 A/sec ramp rate, quench the magnet at 3.8 K until 3 quenches have occurred on plateau or a total of 10 quenches have been taken, whichever comes first.

18) Take a strain gage run at 3.8K to  $I_{quench} - 100$  A.

**19) AC LOSS MEASUREMENT**

See attached appendix.

**20) Warm to room temperature.** Monitor all strain gages and thermometers at 10 minute logging intervals until  $T > 100$  K, then at 30 minute intervals. Continue to monitor until the magnet is within 5 K of its pretest temperature.
